

LAN950x USB 2.0 to 10/100 Ethernet Controller

Highlights

- Single Chip Hi-Speed USB 2.0 to 10/100 Ethernet Controller
- Integrated 10/100 Ethernet MAC with Full-Duplex Support
- Integrated 10/100 Ethernet PHY with HP Auto-MDIX support
- Integrated USB 2.0 Hi-Speed Device Controller
- Integrated USB 2.0 Hi-Speed PHY
- Implements Reduced Power Operating Modes

Target Applications

- Embedded Systems
- Set-Top Boxes
- PVRs
- CE Devices
- Networked Printers
- USB Port Replicators
- Standalone USB to Ethernet Dongles
- Test Instrumentation
- Industrial

Key Features

- USB Device Controller
 - Fully compliant with Hi-Speed Universal Serial Bus Specification Revision 2.0
 - Supports HS (480 Mbps) and FS (12 Mbps) modes
 - Four endpoints supported
 - Supports vendor specific commands
 - Integrated USB 2.0 PHY
 - Remote wakeup supported
- High-Performance 10/100 Ethernet Controller
 - Fully compliant with IEEE802.3/802.3u
 - Integrated Ethernet MAC and PHY
 - 10BASE-T and 100BASE-TX support
 - Full- and half-duplex support
 - Full- and half-duplex flow control
 - Preamble generation and removal
 - Automatic 32-bit CRC generation and checking
 - Automatic payload padding and pad removal
 - Loop-back modes
 - TCP/UDP/IP/ICMP checksum offload support

- Flexible address filtering modes
 - One 48-bit perfect address
 - 64 hash-filtered multicast addresses
 - Pass all multicast
 - Promiscuous mode
 - Inverse filtering
 - Pass all incoming with status report
 - Wakeup packet support
 - Integrated Ethernet PHY
 - Auto-negotiation
 - Automatic polarity detection and correction
 - HP Auto-MDIX support
 - Link status change wake-up detection
 - Support for 3 status LEDs
 - External MII and Turbo MII support Home-PNA™ and HomePlug® PHY
 - Power and I/Os
 - Various low power modes
 - NetDetach feature increases battery life¹
 - Supports PCI-like PME wake¹
 - 11 GPIOs
 - Supports bus-powered and self-powered operation
 - Integrated power-on reset circuit
 - Single external 3.3v I/O supply
 - Internal core regulator
 - Miscellaneous Features
 - EEPROM Controller
 - Supports custom operation without EEPROM¹
 - IEEE 1149.1 (JTAG) Boundary Scan
 - Requires single 25 MHz crystal
 - Software
 - Windows XP/Vista Driver
 - Linux Driver
 - Win CE Driver
 - MAC OS Driver
 - EEPROM Utility
 - Packaging
 - 56-pin QFN (8x8 mm) RoHS Compliant
- Environmental
- Commercial Temperature Range (0°C to +70°C)
 - Industrial Temperature Range (-40°C to +85°C)

¹ = LAN9500A/LAN9500Ai ONLY

TO OUR VALUED CUSTOMERS

It is our intention to provide our valued customers with the best documentation possible to ensure successful use of your Microchip products. To this end, we will continue to improve our publications to better suit your needs. Our publications will be refined and enhanced as new volumes and updates are introduced.

If you have any questions or comments regarding this publication, please contact the Marketing Communications Department via E-mail at docerrors@microchip.com. We welcome your feedback.

Most Current Data Sheet

To obtain the most up-to-date version of this data sheet, please register at our Worldwide Web site at:

<http://www.microchip.com>

You can determine the version of a data sheet by examining its literature number found on the bottom outside corner of any page. The last character of the literature number is the version number, (e.g., DS30000000A is version A of document DS30000000).

Errata

An errata sheet, describing minor operational differences from the data sheet and recommended workarounds, may exist for current devices. As device/documentation issues become known to us, we will publish an errata sheet. The errata will specify the revision of silicon and revision of document to which it applies.

To determine if an errata sheet exists for a particular device, please check with one of the following:

- Microchip's Worldwide Web site; <http://www.microchip.com>
- Your local Microchip sales office (see last page)

When contacting a sales office, please specify which device, revision of silicon and data sheet (include -literature number) you are using.

Customer Notification System

Register on our web site at www.microchip.com to receive the most current information on all of our products.

LAN950x

1.0 LAN950X FAMILY DIFFERENCES OVERVIEW

The Microchip LAN950x is a family of high performance Hi-Speed USB 2.0 to 10/100 Ethernet controllers. The “x” in the part number is a generic term referring to the entire family, which includes the following devices:

- LAN9500
- LAN9500i
- LAN9500A
- LAN9500Ai

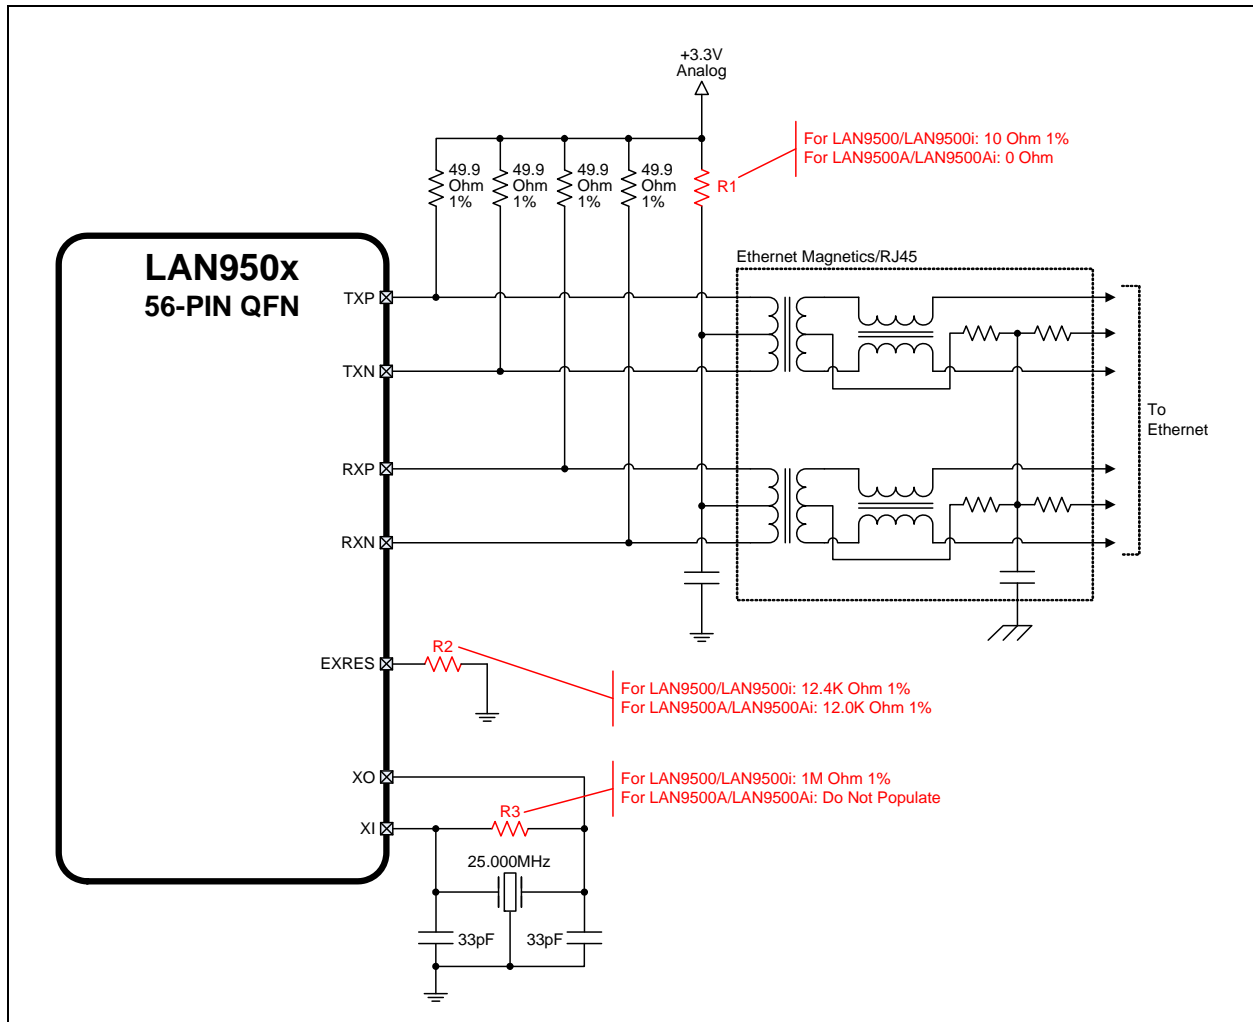

Device specific features that do not pertain to the entire LAN950x family are called out independently throughout this document. [Table 1-1](#) provides a summary of the feature differences between family members.

TABLE 1-1: LAN950X FAMILY DIFFERENCES

| Part Number | PME Wake | Net Detach | Suspend3 State | Good Packet Wakeup | PHY Boost | Custom Operation without EEPROM | Increased Wakeup Frame Filter | Low Power 100uW Crystal Support | 0° To 70°C | -40° to 85°C |
|-------------|----------|------------|----------------|--------------------|-----------|---------------------------------|-------------------------------|---------------------------------|------------|--------------|
| LAN9500 | | | | | | | | | X | |
| LAN9500i | | | | | | | | | | X |
| LAN9500A | X | X | X | X | X | X | X | X | X | |
| LAN9500Ai | X | X | X | X | X | X | X | X | | X |

The LAN9500/LAN9500i and LAN9500A/LAN9500Ai are pin compatible. However, the value of the required EXRES resistor and other system components differ between devices. Refer to [Figure 1-1](#) and the LAN950x reference schematics for additional information.

FIGURE 1-1: SYSTEM COMPONENT DIFFERENCES

2.0 INTRODUCTION

2.1 General Terms and Conventions

The following is a list of the general terms used in this document:

| | |
|-----------------------------------|--|
| BYTE | 8-bits |
| CSR | Control and Status Registers |
| DWORD | 32-bits |
| FIFO | First In First Out buffer |
| Frame | In the context of this document, a frame refers to transfers on the Ethernet interface. |
| FSM | Finite State Machine |
| GPIO | General Purpose I/O |
| HOST | External system (Includes processor, application software, etc.) |
| Level-Triggered Sticky Bit | This type of status bit is set whenever the condition that it represents is asserted. The bit remains set until the condition is no longer true, and the status bit is cleared by writing a zero. |
| LFSR | Linear Feedback Shift Register |
| MAC | Media Access Controller |
| MII | Media Independent Interface |
| N/A | Not Applicable |
| Packet | In the context of this document, a packet refers to transfers on the USB interface. |
| POR | Power on Reset. |
| RESERVED | Refers to a reserved bit field or address. Unless otherwise noted, reserved bits must always be zero for write operations. Unless otherwise noted, values are not guaranteed when reading reserved bits. Unless otherwise noted, do not read or write to reserved addresses. |
| SCSR | System Control and Status Registers |
| SMI | Serial Management Interface |
| TLI | Transaction Layer Interface |
| URX | USB Bulk Out Packet Receiver |
| UTX | USB Bulk In Packet Transmitter |
| WORD | 16-bits |
| ZLP | Zero Length USB Packet |

2.2 Block Diagram

FIGURE 2-1: LAN950X BLOCK DIAGRAM

FIGURE 2-2: LAN950X SYSTEM DIAGRAM

LAN950x

2.2.1 OVERVIEW

The LAN950x is a high performance solution for USB to 10/100 Ethernet port bridging. With applications ranging from embedded systems, set-top boxes, and PVRs, to USB port replicators, USB to Ethernet dongles, and test instrumentation, the device is targeted as a high performance, low cost USB/Ethernet connectivity solution.

The LAN950x contains an integrated 10/100 Ethernet PHY, USB PHY, Hi-Speed USB 2.0 device controller, 10/100 Ethernet MAC, TAP controller, EEPROM controller, and a FIFO controller with a total of 30 KB of internal packet buffering. Two KB of buffer memory are allocated to the Transaction Layer Interface (TLI), while 28 KB are allocated to the FIFO Controller (FCT).

The internal USB 2.0 device controller and USB PHY are compliant with the USB 2.0 Hi-Speed standard. The device implements Control, Interrupt, Bulk-in, and Bulk-out USB Endpoints.

The Ethernet controller supports auto-negotiation, auto-polarity correction, HP Auto-MDIX, and is compliant with the IEEE 802.3 and IEEE 802.3u standards. An external MII interface provides support for an external Fast Ethernet PHY, HomePNA, and HomePlug functionality.

Multiple power management features are provided, including various low power modes and “Magic Packet”, “Wake On LAN”, and “Link Status Change” wake events. These wake events can be programmed to initiate a USB remote wakeup.

An internal EEPROM controller exists to load various USB configuration information and the device MAC address. The integrated IEEE 1149.1 compliant TAP controller provides boundary scan via JTAG.

2.2.2 USB

The USB portion of LAN950x consists of the USB Device Controller (UDC), USB Bulk Out Packet Receiver (URX), USB Bulk In Packet Transmitter (UTX), Control Block (CTL), System Control and Status Registers (SCSR), and USB PHY.

The USB device controller (UDC) contains a USB low-level protocol interpreter that controls the USB bus protocol, packet generation/extraction, PID/Device ID parsing, and CRC coding/decoding with autonomous error handling. It is capable of operating either in USB 1.1 or 2.0 compliant modes. It has autonomous protocol handling functions like stall condition clearing on setup packets, suspend/resume/reset conditions, and remote wakeup. It also autonomously handles contingency operations for error conditions such as retry for CRC errors, Data toggle errors, and generation of NYET, STALL, ACK and NACK depending on the endpoint buffer status. The UDC implements four USB endpoints: Control, Interrupt, Bulk-In, and Bulk-Out.

The Control block (CTL) manages traffic to/from the control endpoint that is not handled by the UDC and constructs the packets used by the interrupt endpoint. The CTL is responsible for handling some USB standard commands and all vendor specific commands. The vendor specific commands allow for efficient statistics collection and access to the SCSR.

The URX and UTX implement the bulk-out and bulk-in pipes, respectively, which connect the USB Host and the UDC. They perform the following functions:

The URX passes USB Bulk-Out packets to the FIFO Controller (FCT). It tracks whether or not a USB packet is erroneous. It instructs the FCT to flush erroneous packets by rewinding its write pointer.

The UTX retrieves Ethernet frames from the FCT and constructs USB Bulk-In packets from them. If the handshake for a transmitted Bulk-In packet does not complete, the UTX is capable of retransmitting the packet. The UTX will not instruct the FCT to advance its read head pointer until the current USB packet has been successfully transmitted to the USB Host.

Both the URX and UTX are responsible for handling Ethernet frames encapsulated over USB by one of the following methods.

- Multiple Ethernet frames per USB Bulk packet
- Single Ethernet frame per USB Bulk packet

The UDC also implements the System Control and Status Register (SCSR) space used by the Host to obtain status and control overall system operation.

The integrated USB 2.0 compliant device PHY supports high speed and full speed modes.

2.2.3 FIFO CONTROLLER (FCT)

The FIFO controller uses a 28 KB internal SRAM to buffer RX and TX traffic. 20 KB is allocated for received Ethernet-USB traffic (RX buffer), while 8 KB is allocated for USB-Ethernet traffic (TX buffer). Bulk-Out packets from the USB controller are directly stored into the TX buffer. The FCT is responsible for extracting Ethernet frames from the USB packet data and passing the frames to the MAC. Ethernet Frames are directly stored into the RX buffer and become the basis for bulk-in packets. The FCT passes the stored data to the UTX in blocks typically 512 or 64 bytes in size, depending on the current HS/FS USB operating speed.

2.2.4 ETHERNET

LAN950x integrates an IEEE 802.3 PHY for twisted pair Ethernet applications and a 10/100 Ethernet Media Access Controller (MAC).

The PHY can be configured for either 100 Mbps (100Base-TX) or 10 Mbps (10Base-T) Ethernet operation in either Full or Half Duplex configurations. The PHY block includes auto-negotiation, auto-polarity correction, and Auto-MDIX. Minimal external components are required for the utilization of the Integrated PHY.

Optionally, an external PHY may be used via the MII (Media Independent Interface) port, effectively bypassing the internal PHY. This option allows support for HomePNA and HomePlug applications.

The transmit and receive data paths within the 10/100 Ethernet MAC are independent, allowing for the highest performance possible, particularly in full-duplex mode. The Ethernet MAC operates in store and forward mode, utilizing an independent 2KB buffer for transmitted frames, and a smaller 128 byte buffer for received frames. The Ethernet MAC data paths connect to the FIFO controller. The MAC also implements a Control and Status Register (CSR) space used by the Host to obtain status and control its operation.

The Ethernet MAC/PHY supports numerous power management wakeup features, including “Magic Packet”, “Wake on LAN” and “Link Status Change”. Eight wakeup frame filters are provided by LAN9500A/LAN9500Ai, while four are provided by LAN9500/LAN9500i.

2.2.5 TRANSACTION LAYER INTERFACE (TLI)

The TLI interfaces the MAC with the FCT. It is a conduit between these two modules through which all transmitted and received data, along with status information, is passed. It has separate receive and transmit data paths. The TLI contains a 2KB transmit FIFO and a 128-byte receive FIFO. The transmit FIFO operates in store and forward mode and is capable of storing up to two Ethernet frames.

2.2.6 POWER MANAGEMENT

The LAN950x features four ([Note 2-1](#)) variations of USB suspend: SUSPEND0, SUSPEND1, SUSPEND2, and SUSPEND3. These modes allow the application to select the ideal balance of remote wakeup functionality and power consumption.

- **SUSPEND0:** Supports GPIO, “Wake On LAN”, and “Magic Packet” remote wakeup events. This suspend state reduces power by stopping the clocks of the MAC and other internal modules.
- **SUSPEND1:** Supports GPIO and “Link Status Change” for remote wakeup events. This suspend state consumes less power than SUSPEND0.
- **SUSPEND2:** Supports only GPIO assertion for a remote wakeup event. This is the default suspend mode for the device.
- **SUSPEND3:** ([Note 2-1](#)) Supports GPIO and “Good Packet” remote wakeup event. A “Good Packet” is a received frame passing certain filtering constraints independent of those imposed on “Wake On LAN” and “Magic Packet” frames. This suspend state consumes power at a level similar to the NORMAL state, however, it allows for power savings in the Host CPU.

Note 2-1 All four SUSPEND states are supported by LAN9500A/LAN9500Ai. SUSPEND3 is not supported by LAN9500/LAN9500i.

Please refer to [Section 5.12, “Wake Events,” on page 100](#) for more information on the USB suspend states and the wake events supported in each state.

LAN950x

2.2.7 EEPROM CONTROLLER (EPC)

LAN950x contains an EEPROM controller for connection to an external EEPROM. This allows for the automatic loading of static configuration data upon power-on reset, pin reset, or software reset. The EEPROM can be configured to load USB descriptors, USB device configuration, and MAC address.

Custom operation without EEPROM is also provided via use of Descriptor RAM and Attributes Registers (LAN9500A/LAN9500Ai ONLY).

2.2.8 GENERAL PURPOSE I/O

When configured for internal PHY mode, up to eleven GPIOs are supported. All GPIOs can serve as remote wakeup events when the LAN950x is in a suspended state.

2.2.9 TAP CONTROLLER

IEEE 1149.1 compliant TAP Controller supports boundary scan and various test modes.

2.2.10 CONTROL AND STATUS REGISTERS (CSR)

LAN950x's functions are controlled and monitored by the Host via the Control and Status Registers (CSR). This register space includes registers that control and monitor the USB controller, as well as elements of overall system operation (System Control and Status Registers - SCSR), the MAC (MAC Control and Status Registers - MCSR), and the PHY (accessed indirectly through the MAC via the MII_ACCESS and MII_DATA registers). The CSR may be accessed via the USB Vendor Commands (REGISTER READ/REGISTER WRITE). Please refer to [Section 5.3.3, "USB Vendor Commands," on page 41](#) for more information.

2.2.11 RESETS

LAN950x supports the following system reset events:

- Power on Reset (POR)
- Hardware Reset Input Pin Reset (nRESET)
- Lite Reset (LRST)
- Software Reset (SRST)
- USB Reset
- VBUS Reset

The device supports the following module level reset events:

- Ethernet PHY Software Reset (PHY_RST)
- nTRST Pin Reset for Tap Controller

2.2.12 TEST FEATURES

Read/Write access to internal SRAMs is provided via the CSRs. JTAG based USB BIST is available. Full internal scan and At Speed scan are supported.

2.2.13 SYSTEM SOFTWARE

LAN950x software drivers are available for the following operating systems:

- Windows XP
- Windows Vista
- Linux
- Win CE
- MAC OS

In addition, an EEPROM programming utility is available for configuring the external EEPROM.

3.0 PIN DESCRIPTION AND CONFIGURATION

FIGURE 3-1: PIN ASSIGNMENTS (TOP VIEW)

- Note 1:** ** This pin is a no-connect (NC) for LAN9500A/LAN9500Ai, but may be connected to VDD33A for backward compatibility with LAN9500/LAN9500i.
- 2:** *** For LAN9500A/LAN9500Ai this pin provides additional PME related functionality. Refer to the respective pin descriptions and [Section 6.0, "PME Operation,"](#) on page 112 for additional information.
- 3:** **** For LAN9500A/LAN9500Ai GPIO7 may provide additional PHY Link Up related functionality. Refer to [Section 5.12.2.4, "Enabling PHY Link Up Wake Events \(LAN9500A/LAN9500Ai ONLY\),"](#) on page 108 for additional information.
- 4:** When HP Auto-MDIX is activated, the TXN/TXP pins can function as RXN/RXP and vice-versa.
- 5:** Exposed pad (VSS) on bottom of package must be connected to ground.

LAN950x

TABLE 3-1: MII INTERFACE PINS

| Num Pins | Name | Symbol | Buffer Type | Description |
|----------|--|--------|----------------|---|
| 1 | Receive Error (Internal PHY Mode) | RXER | IS/O8 (PD) | In internal PHY mode, this pin can be configured to display the respective internal MII signal. Refer to the Internal MII Visibility Enable (IME) bit of the Hardware Configuration Register (HW_CFG) on page 122 for additional information. |
| | Receive Error (External PHY Mode) | RXER | IS (PD) | In external PHY mode, the signal on this pin is input from the external PHY and indicates a receive error in the packet. |
| 1 | Transmit Enable (Internal PHY Mode) | TXEN | IS/O8 (PD) | In internal PHY mode, this pin can be configured to display the respective internal MII signal. Refer to the Internal MII Visibility Enable (IME) bit of the Hardware Configuration Register (HW_CFG) on page 122 for additional information. |
| | Transmit Enable (External PHY Mode) | TXEN | O8 (PD) | In external PHY mode, this pin functions as an output to the external PHY and indicates valid data on TXD[3:0]. |
| 1 | Receive Data Valid (Internal PHY Mode) | RXDV | IS/O8 (PD) | In internal PHY mode, this pin can be configured to display the respective internal MII signal. Refer to the Internal MII Visibility Enable (IME) bit of the Hardware Configuration Register (HW_CFG) on page 122 for additional information. |
| | Receive Data Valid (External PHY Mode) | RXDV | IS (PD) | In external PHY mode, the signal on this pin is input from the external PHY and indicates valid data on RXD[3:0]. |
| 1 | Receive Clock (Internal PHY Mode) | RXCLK | IS/O8 (PD) | In internal PHY mode, this pin can be configured to display the respective internal MII signal. Refer to the Internal MII Visibility Enable (IME) bit of the Hardware Configuration Register (HW_CFG) on page 122 for additional information. |
| | Receive Clock (External PHY Mode) | RXCLK | IS (PD) | In external PHY mode, this pin is the receiver clock input from the external PHY. |
| 1 | Carrier Sense (Internal PHY Mode) | CRS | IS/O8 (PU) | In internal PHY mode, this pin can be configured to display the respective internal MII signal. Refer to the Internal MII Visibility Enable (IME) bit of the Hardware Configuration Register (HW_CFG) on page 122 for additional information. |
| | Carrier Sense (External PHY Mode) | CRS | IS (PD) | In external PHY mode, the signal on this pin is input from the external PHY and indicates a network carrier. |
| | General Purpose I/O 3 (Internal PHY Mode Only) | GPIO3 | IS/O8/OD8 (PU) | This General Purpose I/O pin is fully programmable as either a push-pull output, an open-drain output, or a Schmitt-triggered input. |

TABLE 3-1: MII INTERFACE PINS (CONTINUED)

| Num Pins | Name | Symbol | Buffer Type | Description |
|----------|---|--------------|-----------------------|--|
| 1 | MII Collision Detect (Internal PHY Mode) | COL | IS/O8 (PU) | In internal PHY mode, this pin can be configured to display the respective internal MII signal. Refer to the Internal MII Visibility Enable (IME) bit of the Hardware Configuration Register (HW_CFG) on page 122 for additional information. |
| | MII Collision Detect (External PHY Mode) | COL | IS (PD) | In external PHY mode, the signal on this pin is input from the external PHY and indicates a collision event. |
| | General Purpose I/O 0 (Internal PHY Mode Only) | GPIO0 | IS/O8/ OD8 (PU) | This General Purpose I/O pin is fully programmable as either a push-pull output, an open-drain output, or a Schmitt-triggered input. Note: (LAN9500A/LAN9500Ai ONLY): This pin may be used to signal PME when Internal PHY and PME modes of operation are in effect. Refer to Section 6.0, "PME Operation," on page 112 for additional information. |
| 1 | Management Data (Internal PHY Mode) | MDIO | IS/O8 (PU) | In internal PHY mode, this pin can be configured to display the respective internal MII signal. Refer to the Internal MII Visibility Enable (IME) bit of the Hardware Configuration Register (HW_CFG) on page 122 for additional information. |
| | Management Data (External PHY Mode) | MDIO | IS/O8 (PD) | In external PHY mode, this pin provides the management data to/from the external PHY. |
| | General Purpose I/O 1 (Internal PHY Mode Only) | GPIO1 | IS/O8/ OD8 (PU) | This General Purpose I/O pin is fully programmable as either a push-pull output, an open-drain output, or a Schmitt-triggered input. Note: (LAN9500A/LAN9500Ai ONLY): This pin may serve as the PME_MODE_SEL input when Internal PHY and PME modes of operation are in effect. Refer to Section 6.0, "PME Operation," on page 112 for additional information. |
| 1 | Management Clock (Internal PHY Mode) | MDC | IS/O8 (PU) | In internal PHY mode, this pin can be configured to display the respective internal MII signal. Refer to the Internal MII Visibility Enable (IME) bit of the Hardware Configuration Register (HW_CFG) on page 122 for additional information. |
| | Management Clock (External PHY Mode) | MDC | O8 (PD) | In external PHY mode, this pin outputs the management clock to the external PHY. |
| | General Purpose I/O 2 (Internal PHY Mode Only) | GPIO2 | IS/O8/ OD8 (PU) | This General Purpose I/O pin is fully programmable as either a push-pull output, an open-drain output, or a Schmitt-triggered input. |

LAN950x

TABLE 3-1: MII INTERFACE PINS (CONTINUED)

| Num Pins | Name | Symbol | Buffer Type | Description |
|----------|---|-----------|-----------------------|--|
| 1 | Transmit Data 3 (Internal PHY Mode) | TXD3 | IS/O8 (PU) | In internal PHY mode, this pin can be configured to display the respective internal MII signal. Refer to the Internal MII Visibility Enable (IME) bit of the Hardware Configuration Register (HW_CFG) on page 122 for additional information. |
| | Transmit Data 3 (External PHY Mode) | TXD3 | O8 (PU) | In external PHY mode, this pin functions as the transmit data 3 output to the external PHY. |
| | General Purpose I/O 7 (Internal PHY Mode Only) | GPIO7 | IS/O8/ OD8 (PU) | This General Purpose I/O pin is fully programmable as either a push-pull output, an open-drain output, or a Schmitt-triggered input. Note: (LAN9500A/LAN9500Ai ONLY): GPIO7 may provide additional PHY Link Up related functionality. Refer to Section 5.12.2.4, "Enabling PHY Link Up Wake Events (LAN9500A/LAN9500Ai ONLY)," on page 108 for additional information. |
| | EEPROM Size Configuration Strap | EEP_SIZE | IS (PU) | The EEP_SIZE strap selects the size of the EEPROM attached to the device. 0 = 128 byte EEPROM is attached and a total of seven address bits are used. 1 = 256/512 byte EEPROM is attached and a total of nine address bits are used. Note: A 3-wire style 1K/2K/4K EEPROM that is organized for 128 x 8-bit or 256/512 x 8-bit operation must be used. See Note 3-1 for more information on configuration straps. |
| 1 | Transmit Data 2 (Internal PHY Mode) | TXD2 | IS/O8 (PD) | In internal PHY mode, this pin can be configured to display the respective internal MII signal. Refer to the Internal MII Visibility Enable (IME) bit of the Hardware Configuration Register (HW_CFG) on page 122 for additional information. |
| | Transmit Data 2 (External PHY Mode) | TXD2 | O8 (PD) | In external PHY mode, this pin functions as the transmit data 2 output to the external PHY. |
| | General Purpose I/O 6 (Internal PHY Mode Only) | GPIO6 | IS/O8/ OD8 (PU) | This General Purpose I/O pin is fully programmable as either a push-pull output, an open-drain output, or a Schmitt-triggered input. |
| | USB Port Swap Configuration Strap | PORT_SWAP | IS (PD) | Swaps the mapping of USBDP and USBDM. 0 = USBDP maps to the USB D+ line and USBDM maps to the USB D- line. 1 = USBDP maps to the USB D- line. USBDM maps to the USB D+ line. See Note 3-1 for more information on configuration straps. |

TABLE 3-1: MII INTERFACE PINS (CONTINUED)

| Num Pins | Name | Symbol | Buffer Type | Description |
|----------|---|--------------------|-----------------------|--|
| 1 | Transmit Data 1 (Internal PHY Mode) | TXD1 | IS/O8 (PD) | In internal PHY mode, this pin can be configured to display the respective internal MII signal. Refer to the Internal MII Visibility Enable (IME) bit of the Hardware Configuration Register (HW_CFG) on page 122 for additional information. |
| | Transmit Data 1 (External PHY Mode) | TXD1 | O8 (PD) | In external PHY mode, this pin functions as the transmit data 1 output to the external PHY. |
| | General Purpose I/O 5 (Internal PHY Mode Only) | GPIO5 | IS/O8/ OD8 (PU) | This General Purpose I/O pin is fully programmable as either a push-pull output, an open-drain output, or a Schmitt-triggered input. |
| | Remote Wakeup Configuration Strap | RMT_WKP | IS (PD) | This strap configures the default descriptor values to support remote wakeup. This strap is overridden by the EEPROM. 0 = Remote wakeup is not supported. 1 = Remote wakeup is supported. See Note 3-1 for more information on configuration straps. |
| 1 | Transmit Data 0 (Internal PHY Mode) | TXD0 | IS/O8 (PD) | In internal PHY mode, this pin can be configured to display the respective internal MII signal. Refer to the Internal MII Visibility Enable (IME) bit of the Hardware Configuration Register (HW_CFG) on page 122 for additional information. |
| | Transmit Data 0 (External PHY Mode) | TXD0 | O8 (PD) | In external PHY mode, this pin functions as the transmit data 0 output to the external PHY. |
| | General Purpose I/O 4 (Internal PHY Mode Only) | GPIO4 | IS/O8/ OD8 (PU) | This General Purpose I/O pin is fully programmable as either a push-pull output, an open-drain output, or a Schmitt-triggered input. |
| | EEPROM Disable Configuration Strap | EEP_DISABLE | IS (PD) | This strap disables the autoloading of the EEPROM contents. The assertion of this strap does not prevent register access to the EEPROM. 0 = EEPROM is recognized if present. 1 = EEPROM is not recognized even if it is present. See Note 3-1 for more information on configuration straps. |
| 1 | Transmit Clock (Internal PHY Mode) | TXCLK | IS/O8 (PU) | In internal PHY mode, this pin can be configured to display the respective internal MII signal. Refer to the Internal MII Visibility Enable (IME) bit of the Hardware Configuration Register (HW_CFG) on page 122 for additional information. |
| | Transmit Clock (External PHY Mode) | TXCLK | IS (PU) | In external PHY mode, this pin is the transmitter clock input from the external PHY. |

Note 3-1 Configuration strap values are latched on [Power-On Reset \(POR\)](#) or [External Chip Reset \(nRESET\)](#). Configuration straps are identified by an underlined symbol name. Pins that function as configuration straps must be augmented with an external resistor when connected to a load. Refer to [Section 5.14, "Configuration Straps,"](#) on [page 110](#) for additional information.

LAN950x

TABLE 3-2: EEPROM PINS

| Num Pins | Name | Symbol | Buffer Type | Description |
|----------|--------------------------------------|--------------------|-------------|---|
| 1 | EEPROM Data In | EEDI | IS (PD) | This pin is driven by the EEDO output of the external EEPROM. |
| 1 | EEPROM Data Out | EEDO | O8 (PU) | This pin drives the EEDI input of the external EEPROM. |
| | Auto-MDIX Enable Configuration Strap | AUTOMDIX_EN | IS (PU) | Determines the default Auto-MDIX setting. 0 = Auto-MDIX is disabled. 1 = Auto-MDIX is enabled. See Note 3-2 for more information on configuration straps. |
| 1 | EEPROM Chip Select | EECS | O8 | This pin drives the chip select output of the external EEPROM. Note: The EECS output may tri-state briefly during power-up. Some EEPROM devices may be prone to false selection during this time. When an EEPROM is used, an external pull-down resistor is recommended on this signal to prevent false selection. Refer to your EEPROM manufacturer's data sheet for additional information. |
| 1 | EEPROM Clock | EECLK | O8 (PD) | This pin drives the EEPROM clock of the external EEPROM. |
| | Power Select Configuration Strap | PWR_SEL | IS (PD) | Determines the default power setting when no EEPROM is present. This strap is overridden by the EEPROM. 0 = The device is bus powered. 1 = The device is self powered. See Note 3-2 for more information on configuration straps. |

Note 3-2 Configuration strap values are latched on [Power-On Reset \(POR\)](#) or [External Chip Reset \(nRESET\)](#). Configuration straps are identified by an underlined symbol name. Pins that function as configuration straps must be augmented with an external resistor when connected to a load. Refer to [Section 5.14, "Configuration Straps,"](#) on page 110 for additional information.

TABLE 3-3: JTAG PINS

| Num Pins | Name | Symbol | Buffer Type | Description |
|----------|--|----------|-------------|--|
| 1 | JTAG Test Port Reset (Internal PHY Mode) | nTRST | IS (PU) | In internal PHY mode, this active-low pin functions as the JTAG test port reset input. |
| | Receive Data 0 (External PHY Mode) | RXD0 | IS (PD) | In external PHY mode, this pin functions as the receive data 0 input from the external PHY. |
| 1 | JTAG Test Data Out (Internal PHY Mode) | TDO | O8 | In internal PHY mode, this pin functions as the JTAG data output. |
| | PHY Reset (External PHY Mode) | nPHY_RST | O8 | In external PHY mode, this active-low pin functions as the PHY reset output. |
| 1 | JTAG Test Clock (Internal PHY Mode) | TCK | IS (PU) | In internal PHY mode, this pin functions as the JTAG test clock. The maximum operating frequency of this clock is 25MHz. |
| | Receive Data 1 (External PHY Mode) | RXD1 | IS (PD) | In external PHY mode, this pin functions as the receive data 1 input from the external PHY. |
| 1 | JTAG Test Mode Select (Internal PHY Mode) | TMS | IS (PU) | In internal PHY mode, this pin functions as the JTAG test mode select. |
| | Receive Data 2 (External PHY Mode) | RXD2 | IS (PD) | In external PHY mode, this pin functions as the receive data 2 input from the external PHY. |
| 1 | JTAG Test Data Input (Internal PHY Mode) | TDI | IS (PU) | In internal PHY mode, this pin functions as the JTAG data input. |
| | Receive Data 3 (External PHY Mode) | RXD3 | IS (PD) | In external PHY mode, this pin functions as the receive data 3 input from the external PHY. |

LAN950x

TABLE 3-4: MISCELLANEOUS PINS

| Num Pins | Name | Symbol | Buffer Type | Description |
|----------|--------------------------------------|-----------|------------------|---|
| 1 | PHY Select | PHY_SEL | IS (PD) | <p>Selects whether to use the internal Ethernet PHY or the external PHY connected to the MII port.</p> <p>0 = Internal PHY is used. 1 = External PHY is used.</p> <p>Note: When in external PHY mode, the internal PHY is placed into general power down after a POR. Please Refer to Section 5.6, "10/100 Internal Ethernet PHY," on page 69 for details.</p> |
| 1 | System Reset | nRESET | IS (PU) | <p>This active-low pin allows external hardware to reset the device.</p> <p>Note: (LAN9500A/LAN9500Ai ONLY): This pin may be used to signal PME_CLEAR when PME mode of operation is in effect. Refer to Section 6.0, "PME Operation," on page 112 for additional information.</p> |
| 1 | Ethernet Full-Duplex Indicator LED | nFDX_LED | OD12 (PU) | <p>This pin is driven low (LED on) when the Ethernet link is operating in full-duplex mode.</p> |
| | General Purpose I/O 8 | GPIO8 | IS/O12/OD12 (PU) | <p>This General Purpose I/O pin is fully programmable as either a push-pull output, an open-drain output, or a Schmitt-triggered input.</p> <p>Note 1: (LAN9500A/LAN9500Ai ONLY): This pin may be used to signal PME when External PHY and PME modes of operation are in effect. Refer to Section 6.0 "PME Operation" for additional information.</p> <p>2: By default this pin is configured as a GPIO.</p> |
| 1 | Ethernet Link Activity Indicator LED | nLNKA_LED | OD12 (PU) | <p>This pin is driven low (LED on) when a valid link is detected. This pin is pulsed high (LED off) for 80mS whenever transmit or receive activity is detected. This pin is then driven low again for a minimum of 80mS, after which time it will repeat the process if TX or RX activity is detected. Effectively, LED2 is activated solid for a link. When transmit or receive activity is sensed, LED2 will function as an activity indicator.</p> |
| | General Purpose I/O 9 | GPIO9 | IS/O12/OD12 (PU) | <p>This General Purpose I/O pin is fully programmable as either a push-pull output, an open-drain output, or a Schmitt-triggered input.</p> <p>Note 1: (LAN9500A/LAN9500Ai ONLY): This pin may serve as the PME_MODE_SEL input when External PHY and PME modes of operation are in effect. Refer to Section 6.0 "PME Operation" for additional information.</p> <p>2: By default this pin is configured as a GPIO.</p> |

TABLE 3-4: MISCELLANEOUS PINS (CONTINUED)

| Num Pins | Name | Symbol | Buffer Type | Description |
|----------|------------------------------|---------------|------------------|---|
| 1 | Ethernet Speed Indicator LED | nSPD_LED | OD12 (PU) | This pin is driven low (LED on) when the Ethernet operating speed is 100Mbps, or during auto-negotiation. This pin is driven high during 10Mbps operation, or during line isolation. |
| | General Purpose I/O 10 | GPIO10 | IS/O12/OD12 (PU) | This General Purpose I/O pin is fully programmable as either a push-pull output, an open-drain output, or a Schmitt-triggered input. Note 1: (LAN9500A/LAN9500Ai ONLY): This pin may serve as a wakeup pin whose detection mode is selectable when External PHY and PME modes of operation are in effect. Refer to Section 6.0 "PME Operation" for additional information. 2: By default this pin is configured as a GPIO. |
| 1 | Detect Upstream VBUS Power | VBUS_DET | IS_5V (PD) | Detects state of upstream bus power. For bus powered applications, this pin must be tied to VDD33IO. For self powered applications where the device is permanently attached to a host, VBUS_DET should be pulled to VDD33IO. For other self powered applications, refer to the device reference schematic for additional connection information. Note: (LAN9500A/LAN9500Ai ONLY): This pin may be used to signal bus power availability when PME mode of operation is in effect. Refer to Section 6.0 "PME Operation" for additional information. |
| 1 | Test 1 | TEST1 | - | This pin must always be connected to VDD33IO for proper operation. |
| 1 | Test 2 | TEST2 | - | This pin must always be connected to VSS for proper operation. |
| 1 | Test 3 | TEST3 | - | This pin must always be connected to VSS for proper operation. |

| EXPOSED PAD MUST BE CONNECTED TO VSS | | | | | | | |

Note 3-3 This pin is a no-connect (NC) for LAN9500A/LAN9500Ai, but may be connected to VDD33A for backward compatibility with LAN9500/LAN9500i.

Note 3-4 For LAN9500A/LAN9500Ai this pin provides additional PME related functionality. Refer to the respective pin descriptions and [Section 6.0, "PME Operation," on page 112](#) for additional information.

3.2 Buffer Types

TABLE 3-10: BUFFER TYPES

| Buffer Type | Description |
|-------------|---|
| IS | Schmitt-triggered Input |
| IS_5V | 5V Tolerant Schmitt-triggered Input |
| O8 | Output with 8mA sink and 8mA source |
| OD8 | Open-drain output with 8mA sink |
| O12 | Output with 12mA sink and 12mA source |
| OD12 | Open-drain output with 12mA sink |
| PU | 50uA (typical) internal pull-up. Unless otherwise noted in the pin description, internal pull-ups are always enabled. Note: Internal pull-up resistors prevent unconnected inputs from floating. Do not rely on internal resistors to drive signals external to the device. When connected to a load that must be pulled high, an external resistor must be added. |
| PD | 50uA (typical) internal pull-down. Unless otherwise noted in the pin description, internal pull-downs are always enabled. Note: Internal pull-down resistors prevent unconnected inputs from floating. Do not rely on internal resistors to drive signals external to the device. When connected to a load that must be pulled low, an external resistor must be added. |
| AI | Analog input |
| AIO | Analog bi-directional |
| ICLK | Crystal oscillator input pin |
| OCLK | Crystal oscillator output pin |
| P | Power pin |

LAN950x

4.0 POWER CONNECTIONS

Figure 4-1 illustrates the power connections for LAN950x.

FIGURE 4-1: POWER CONNECTIONS

5.0 FUNCTIONAL DESCRIPTION

5.1 Functional Overview

The LAN950x USB 2.0 to 10/100 Ethernet Controller consists of the following major functional blocks:

- [USB PHY](#)
- [USB 2.0 Device Controller \(UDC\)](#)
- [FIFO Controller \(FCT\)](#) and Associated SRAM
- [10/100 Ethernet MAC](#)
- [10/100 Internal Ethernet PHY](#)
- IEEE 1149.1 Tap Controller
- [EEPROM Controller \(EPC\)](#)

The following sections discuss the features of each block. A block diagram of the device is shown in [FIGURE 2-1: LAN950x Block Diagram on page 7](#).

5.2 USB PHY

The USB PHY has the USB interface on one end, and connects to the USB 2.0 Device Controller on the other. The Parallel-to-serial/serial-to-parallel conversion, bit stuffing, and NRZI coding / decoding are handled in the PHY block. The PHY is capable of operating in the USB 1.1 and 2.0 modes.

5.3 USB 2.0 Device Controller (UDC)

The USB functionality in the device consists of five major parts. The USB PHY (discussed in [Section 5.2](#)), UCB (USB Common Block), UDC (USB Device Controller), URX (USB Bulk Out Receiver), UTX (USB Bulk In Receiver), and CTL (USB Control Block). They are represented as the USB PHY and UDC, collectively, in [FIGURE 2-1: LAN950x Block Diagram on page 7](#).

The UCB generates various clocks, including the system clocks of the device. The URX and UTX implement the Bulk Out and Bulk In endpoints respectively. The CTL manages control and interrupt endpoints.

The UDC is a USB low-level protocol interpreter. The UDC controls the USB bus protocol, packet generation/extraction, PID/Device ID parsing, and CRC coding/decoding with autonomous error handling. It is capable of operating either in USB 1.1 or 2.0 compliant modes. It has autonomous protocol handling functions like stall condition clearing on setup packets, suspend/resume/reset conditions, and remote wakeup. It also autonomously handles error conditions such as retry for CRC errors, Data toggle errors, and generation of NYET, STALL, ACK and NACK, depending on the endpoint buffer status.

The UDC is configured to support one configuration, one interface, one alternate setting, and four endpoints.

5.3.1 SUPPORTED ENDPOINTS

[Table 5-1](#) lists the supported endpoints. The following subsections discuss these endpoints in detail.

TABLE 5-1: SUPPORTED ENDPOINTS

| Endpoint Number | Description |
|-----------------|--------------------|
| 0 | Control Endpoint |
| 1 | Bulk In Endpoint |
| 2 | Bulk Out Endpoint |
| 3 | Interrupt Endpoint |

The URX and UTX implement the Bulk Out and Bulk In endpoints, respectively. The CTL manages the Control and Interrupt endpoints.

LAN950x

5.3.1.1 Endpoint 1 (Bulk In)

The Bulk In Endpoint is controlled by the UTX (USB Bulk In Transmitter). The UTX is responsible for encapsulating Ethernet data into a USB Bulk In packet. Ethernet frames are retrieved from the FCT's RX FIFO.

The UTX supports the following two modes of operation: MEF and SEF, selected via the [Multiple Ethernet Frames per USB Packet \(MEF\)](#) bit of the [Hardware Configuration Register \(HW_CFG\)](#).

- MEF: Multiple Ethernet frames per Bulk In packet. This mode will maximize USB bus utilization by allowing multiple Ethernet frames to be packed into a USB packet. Frames greater than 512 bytes are split across multiple Bulk In packets.
- SEF: Single Ethernet frame per Bulk In packet. This mode will not maximize USB bus utilization, but can potentially ease the burden on a low end host processor. Frames greater than 512 bytes are split across multiple Bulk In packets.

Each Ethernet frame is prepended with an RX Status Word by the FCT. The status word contains the frame length that is used by the UTX to perform the encapsulation functions. The RX Status word is generated by the RX Transaction Layer Interface (RX TLI). The TLI resides between the MAC and the FCT.

Padding may be inserted between the RX Status Word and the Ethernet frame by the FCT. This condition exists when the RXDOFF register has a nonzero value (refer to [Section 7.3.5, "Hardware Configuration Register \(HW_CFG\)"](#) for details). The padding is implemented by the FCT barrel shifting the Ethernet frame by the specified byte offset.

FIGURE 5-1: MEF USB ENCAPSULATION (LAN9500/LAN9500I AND LAN9500A/LAN9500AI ONLY)

In accordance with the USB protocol, the UTX terminates a burst with either a ZLP or a Bulk In packet with a size of less than the Bulk In maximum packet size (512 for HS, 64 for FS). The ZLP is needed when the total amount of data transmitted is a multiple of a Bulk In packet size. The UTX monitors the RX FIFO size signal from the FCT to determine when a burst has ended.

Note: In SEF mode, a ZLP is transmitted if the Ethernet frame is the same size as a Bulk In packet, or a multiple of the Bulk In packet size.

An Ethernet frame always begins on a DWORD boundary. In MEF mode, the UTX will not concatenate the end of the current frame and the beginning of the next frame into the same DWORD. Therefore, the last DWORD of an Ethernet frame may have unused bytes added to ensure DWORD alignment of the next frame. The addition of pad bytes depends on whether another frame is available for transmission after the current one. If the current frame is the last frame to be transmitted, no pad bytes will be added, as the USB protocol allows for termination of the packet on a byte boundary. If, however, another frame is available for transmission, the current frame will be padded out so that it ends on the DWORD boundary. This ensures the next frame to be transmitted will start on a DWORD boundary.

If the UTX receives a Bulk In token when the RX FIFO is empty, it will transmit a ZLP.

- Note 1:** Any unused bytes that were added to the last DWORD of a frame are not counted in the length field of the RX status word.
- 2: The Host ignores unused bytes that exist in the first DWORD and last words of an Ethernet frame.
 - 3: When using SEF mode, there will never be any unused bytes added for end alignment padding. The USB transfer always ends on the last byte of the Ethernet frame.
 - 4: When RX COE is enabled, the last byte would pertain to the RX COE word.

Once a decision is made to end a transfer and a short packet or ZLP has been sent, it is possible that an Ethernet frame will arrive prior to the UTX seeing an ACK from the Host for the previous Bulk In packet. In this case, the UTX must continue to repeat the short packet or ZLP until the ACK is received for the end of the previous transfer. The UTX must not start a new transfer, or re-use the previous data toggle, to begin sending the next Ethernet frame until the ACK has been received for the end of the previous transfer.

In order to more efficiently utilize USB bandwidth in MEF mode, the UTX has a mechanism for delaying the transmission of a short packet, or ZLP. This mode entails having the UTX wait a time defined by the [Bulk In Delay Register \(BULK_IN_DLY\)](#) before terminating the burst. A value of zero in this register disables this feature. By default, a delay of 34 us is used.

After the UTX transmits the last USB `wPacketSize` packet in a burst, the UTX will enable an internal timer. When the internal timer is equal to the [Bulk In Delay](#), any Bulk In data will be transmitted upon reception of the next Bulk In Token. If enough data arrives before the timer elapses to build at least one maximum sized packet, then the UTX will transmit this packet when it receives the next Bulk In Token. After packet transmission, the UTX will then reset its internal timer and delay the short packet, or ZLP, transmission until the [Bulk In Delay](#) time elapses.

In the case where the FIFO is empty and a single Ethernet packet less than the USB `wPacketSize` has been received, the UTX will enable its internal timer. If enough data arrives before the timer elapses to build at least one maximum sized packet, then the UTX will transmit this packet when it receives the next Bulk In Token and will reset the internal timer. Otherwise, the short packet, or ZLP, is sent in response to the first Bulk In Token received after the timer expires.

The UTX will NAK any Bulk In tokens while waiting for the [Bulk In Delay](#) to elapse. This NAK response is not affected by the [Bulk In Empty Response \(BIR\)](#). The [Bulk In Empty Response \(BIR\)](#) setting only applies after the [Bulk In Delay](#) time expires.

The UTX, via the [Burst Cap Register \(BURST_CAP\)](#), is capable of prematurely terminating a burst. When the amount transmitted exceeds the value specified in this register, the UTX transmits a ZLP after the current Bulk In packet completes. The [Burst Cap Register \(BURST_CAP\)](#) uses units of USB packet size (512 bytes). To enable use of the Burst Cap register, the [Burst Cap Enable \(BCE\)](#) bit in the [Hardware Configuration Register \(HW_CFG\)](#) must be set. For proper operation, the [BURST_CAP](#) field should be set to value greater than 4 for HS mode and greater than 32 for FS mode. Burst Cap enforcement is disabled if [BURST_CAP](#) is set to a value less than or equal to 4 for HS mode and less than or equal to 32 for FS mode.

Whenever Burst Cap enforcement is disabled, the UTX will respond with a ZLP (when [Bulk In Empty Response \(BIR\)](#) = 0) or with NAK (when [Bulk In Empty Response \(BIR\)](#) = 1).

Whenever Burst Cap enforcement is enabled ([BURST_CAP](#) value is legal), the following holds:

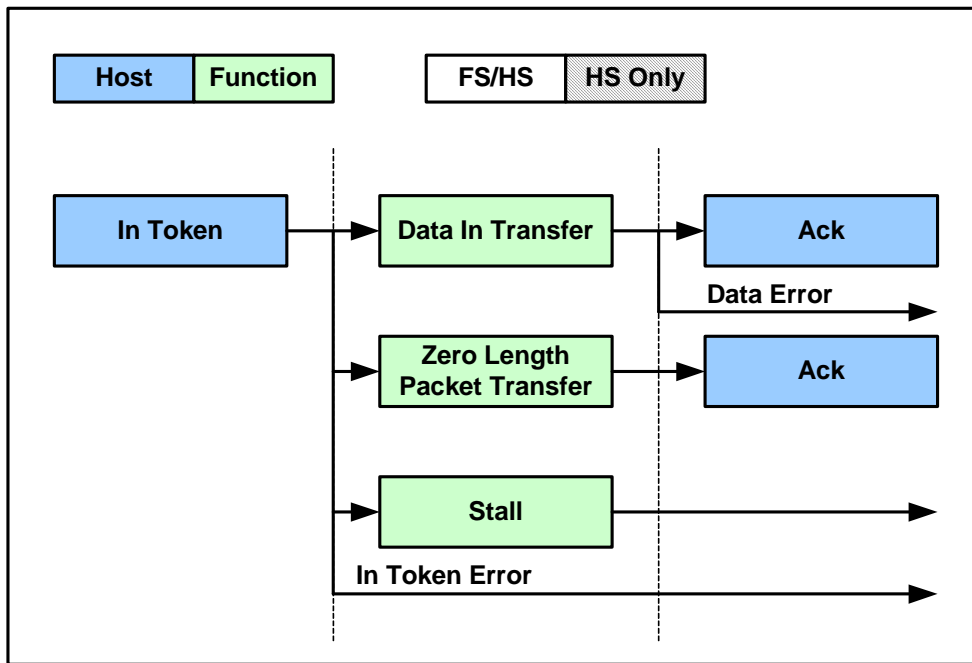

- For HS Operation:
 - Let $BURST = BURST_CAP * 512$
 - The burst may terminate at $BURST-4$, $BURST-3$, $BURST-2$, $BURST-1$, or $BURST$ bytes, or, when the RX FIFO runs out of data. The burst is terminated with either a short USB packet or with a ZLP.
- For FS operation:
 - The burst will terminate after $BURST_CAP * 64$ bytes.

Note: Ethernet frames are not fragmented across bursts when using Burst Cap Enforcement.

In the case of an error condition, the UTX will issue a rewind to the FCT. This occurs when the UTX completes transmitting a Bulk In packet and does not receive an ACK from the Host. In this case, the next frame received by the UTX will be another In token and the Bulk In packet is retransmitted. When the ACK is finally received, the UTX notifies the FCT. The FCT will then advance the read head pointer to the next packet.

Note: The UTX will never stall the endpoint. The endpoint can only be stalled by the Host.

FIGURE 5-2: USB BULK IN TRANSACTION SUMMARY

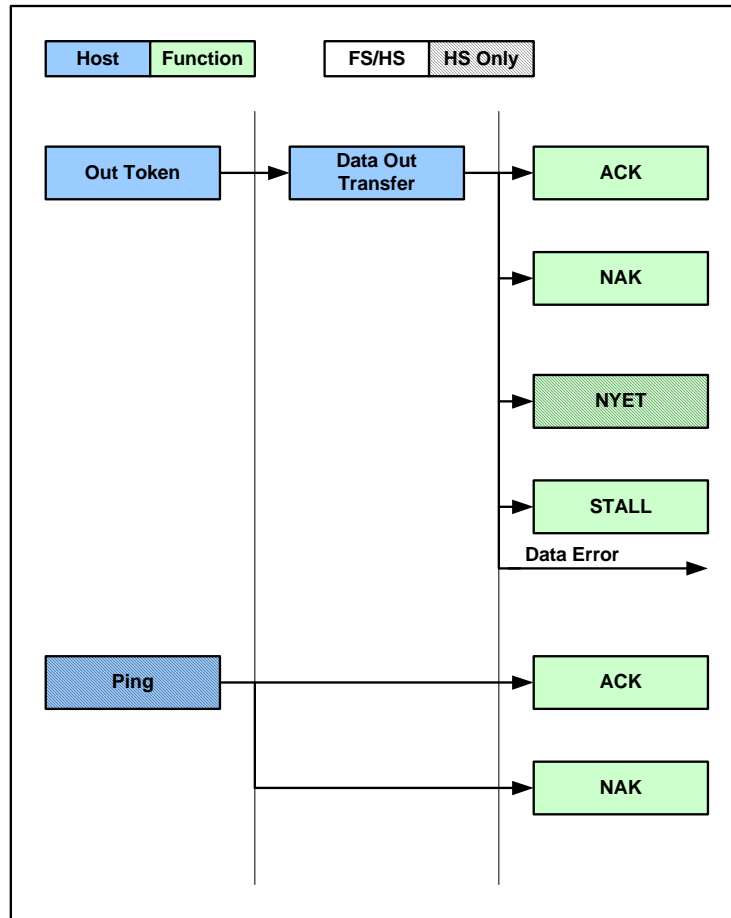

5.3.1.2 Endpoint 2 (Bulk Out)

The Bulk Out Endpoint is controlled by the URX (USB Bulk Out Receiver). The URX is responsible for receiving Ethernet data encapsulated over a USB Bulk Out packet. Unlike the UTX, the URX does not explicitly track Ethernet frames. It views all received packets as purely USB data. The extraction of Ethernet frames is handled by the FCT and the Transaction Layer Interface (TLI).

The URX always simultaneously supports multiple Ethernet frames per USB packet, as well as a single Ethernet frame per USB packet. No mechanism exists to select between modes.

The URX monitors the amount of free space in the TX FIFO. If at least 512 bytes of space exists, the URX can accept an additional Bulk In frame and responds to a Bulk Out Token with an ACK or NYET. The NYET response is used when less than 1024 bytes of free space exists. This means that the current Bulk Out packet was accepted, but room does not exist for a second packet. If less than 512 bytes exists, the URX responds with a NAK. The URX supports the PING protocol.

FIGURE 5-3: USB BULK OUT TRANSACTION SUMMARY

In the case where the Bulk Out packet is errored, the URX does not respond to the Host. The URX will request that the FCT rewinds the packet. It is the Hosts responsibility to retransmit the packet at a later time.

The FCT notifies the URX when it detects loss of sync. When this occurs, the URX stalls the Bulk Out pipe. This is an appropriate response, as loss of sync is a catastrophic error. This behavior is configurable via the [Hardware Configuration Register \(HW_CFG\)](#) on page 122.

LAN950x

5.3.1.3 Endpoint 3 (Interrupt)

The Interrupt endpoint is responsible for indicating device status at each polling interval. The Interrupt endpoint is implemented via the CTL module. When the endpoint is accessed, the Interrupt packet specified in [Table 5-2](#) is presented to the Host.

TABLE 5-2: INTERRUPT PACKET FORMAT

| Bits | Description |
|-------|--|
| 31:20 | RESERVED |
| 19 | MACRTO_INT |
| 18 | RX FIFO Has Frame. The RX FIFO has at least one complete Ethernet frame. |
| 17 | TXSTOP_INT |
| 16 | RXSTOP_INT |
| 15 | PHY_INT |
| 14 | TXE |
| 13 | TDFU |
| 12 | TDFO |
| 11 | RXDF_INT |
| 10:0 | GPIO_INT |

If there is no interrupt status to report, the device responds with a NAK.

Note: The polling interval is static and set through the EEPROM. The Host can change the polling interval by updating the contents of the EEPROM and resetting the part.

The interrupt status can be cleared by writing to [Interrupt Status Register \(INT_STS\)](#) on page 119.

5.3.1.4 Endpoint 0 (Control)

The Control endpoint is handled by the CTL (USB Control) module. The CTL module is responsible for handling USB standard commands, as well as USB vendor commands. In order to support these commands, the CTL must compile a variety of statistics and store the programmable portions of the USB descriptors. The supported USB commands can be found in [Section 5.3.2, "USB Standard Commands,"](#) on page 37.

5.3.1.5 USB Command Processing

The UDC is programmed to decode USB commands. After a standard command is decoded by the UDC, it may be passed to the CTL for completion. The CTL is responsible for implementing the Get Descriptor and vendor commands.

In order to implement the Get Descriptor command for string descriptors, the CTL manages a 128x32 register file which stores the string values for Language ID, Manufacturer ID, Product ID, Serial Number, Configuration, and Interface. The RAM's contents is initialized via the EEPROM, after a system reset occurs.

TABLE 5-3: STRING DESCRIPTOR INDEX MAPPINGS

| Index | String Name |
|-------|----------------------|
| 0 | Language ID |
| 1 | Manufacturer ID |
| 2 | Product ID |
| 3 | Serial Number |
| 4 | Configuration String |
| 5 | Interface String |

When the UDC decodes a Get Descriptor command, it will pass a pointer to the CTL. The CTL uses this pointer to determine what the command is and how to fill it.

5.3.1.6 USB Descriptors

The following subsections describe the USB descriptors.

5.3.1.6.1 Device Descriptor

The Device Descriptors are initialized based on values stored in EEPROM. [Table 5-4](#) shows the default Device Descriptor values. These values are used for both Full-Speed and Hi-Speed operation.

TABLE 5-4: DEVICE DESCRIPTOR

| Offset | Field | Size (Bytes) | Default Value | Loaded from EEPROM | Description |
|--------|--------------------|--------------|--------------------------|--------------------------|--|
| 00h | bLength | 1 | 12h | Note 5-1 | Size of the Descriptor in Bytes (18 bytes) |
| 01h | bDescriptorType | 1 | 01h | Note 5-1 | Device Descriptor (0x01) |
| 02h | bcdUSB | 2 | 0200h | Note 5-2 | USB Specification Number which device complies to. |
| 04h | bDeviceClass | 1 | FFh | Yes | Class Code |
| 05h | bDeviceSubClass | 1 | 00h | Yes | Subclass Code |
| 06h | bDeviceProtocol | 1 | FFh | Yes | Protocol Code |
| 07h | bMaxPacketSize | 1 | 40h | Note 5-2 | Maximum Packet Size for Endpoint 0 |
| 08h | IdVendor | 2 | 0424h | Yes | Vendor ID |
| 0Ah | IdProduct | 2 | Note 5-3 | Yes | Product ID |
| 0Ch | bcdDevice | 2 | Note 5-4 | Yes | Device Release Number |
| 0Eh | iManufacturer | 1 | 00h | Yes | Index of Manufacturer String Descriptor |
| 0Fh | iProduct | 1 | 00h | Yes | Index of Product String Descriptor |
| 10h | iSerialNumber | 1 | 00h | Yes | Index of Serial Number String Descriptor |
| 11h | bNumConfigurations | 1 | 01h | Note 5-2 | Number of Possible Configurations |

Note 5-1 The descriptor length and descriptor type for Device Descriptors specified in EEPROM are “don’t cares” and are always overwritten by hardware as 0x12 and 0x01, respectively.

Note 5-2 Value is loaded from EEPROM, but must be equal to the Default Value in order to comply with the USB 2.0 Specification and provide for normal device operation. Specification of any other value will result in unwanted behavior and untoward operation.

Note 5-3 Product IDs are:

| Product | ID |
|--------------------|-------|
| LAN9500/LAN9500i | 9500h |
| LAN9500A/LAN9500Ai | 9E00h |

Note 5-4 Default value is dependent on device release. MSB matches the device release and LSB hardcoded to 00h. The initial release value is 01h.

LAN950x

5.3.1.6.2 Configuration Descriptor

The Configuration Descriptor is initialized based on values stored in EEPROM. [Table 5-5](#) shows the default Configuration Descriptor values. These values are used for both Full-Speed and Hi-Speed operation.

TABLE 5-5: CONFIGURATION DESCRIPTOR

| Offset | Field | Size (Bytes) | Default Value | Loaded from EEPROM | Description |
|--------|---------------------|--------------|--------------------------|--------------------------|--|
| 00h | bLength | 1 | 09h | Note 5-5 | Size of the Configuration Descriptor in bytes (9 bytes) |
| 01h | bDescriptorType | 1 | 02h | Note 5-6 | Configuration Descriptor (0x02) |
| 02h | wTotalLength | 2 | 0027h | Note 5-5 | Total length in bytes of data returned (39 bytes) |
| 04h | bNumInterfaces | 1 | 01h | Note 5-5 | Number of Interfaces |
| 05h | bConfigurationValue | 1 | 01h | Note 5-5 | Value to use as an argument to select this configuration |
| 06h | iConfiguration | 1 | 00h | Yes | Index of String Descriptor describing this configuration |
| 07h | bmAttributes | 1 | A0h | Yes | Bus powered and remote wakeup enabled. |
| 08h | bMaxPower | 1 | Note 5-7 | Yes | Maximum Power Consumption is 500 mA. |

Note 5-5 Value is loaded from EEPROM, but must be equal to the Default Value in order to comply with the USB 2.0 Specification and provide for normal device operation. Specification of any other value will result in unwanted behavior and untoward operation.

Note 5-6 The descriptor type for Configuration Descriptors specified in EEPROM is a “don’t care” and is always overwritten by hardware as 0x02.

Note 5-7 Default value is 01h in Self Powered mode and FAh in Bus Powered mode.

Note: The PWR_SEL and RMT_WKP straps affect the default value of bmAttributes.

5.3.1.6.3 Interface Descriptor 0 Default

[Table 5-6](#) shows the default value for Interface Descriptor 0. This descriptor is initialized based on values stored in EEPROM.

TABLE 5-6: INTERFACE DESCRIPTOR 0

| Offset | Field | Size (Bytes) | Default Value | Loaded From EEPROM | Description |
|--------|--------------------|--------------|---------------|--------------------------|---|
| 00h | bLength | 1 | 09h | Note 5-8 | Size of Descriptor in Bytes (9 Bytes) |
| 01h | bDescriptorType | 1 | 04h | Note 5-8 | Interface Descriptor (0x04) |
| 02h | bInterfaceNumber | 1 | 00h | Note 5-8 | Number identifying this Interface |
| 03h | bAlternateSetting | 1 | 00h | Note 5-8 | Value used to select alternative setting |
| 04h | bNumEndpoints | 1 | 03h | Note 5-8 | Number of Endpoints used for this interface (Less endpoint 0) |
| 05h | bInterfaceClass | 1 | FFh | Yes | Class Code |
| 06h | bInterfaceSubClass | 1 | 00h | Yes | Subclass Code |
| 07h | bInterfaceProtocol | 1 | FFh | Yes | Protocol Code |
| 08h | iInterface | 1 | 00h | Yes | Index of String Descriptor Describing this interface |

Note 5-8 Value is loaded from EEPROM, but must be equal to the Default Value in order to comply with the USB 2.0 Specification and provide for normal device operation. Specification of any other value will result in unwanted behavior and untoward operation.

5.3.1.6.4 Endpoint 1 (Bulk In) Descriptor

Table 5-7 shows the default value for Endpoint Descriptor 1. This descriptor is not initialized from values stored in EEPROM.

TABLE 5-7: ENDPOINT 1 DESCRIPTOR

| Offset | Field | Size (Bytes) | Default Value | Loaded from EEPROM | Description |
|--------|------------------|--------------|---------------|--------------------|---|
| 00h | bLength | 1 | 07h | No | Size of Descriptor in bytes |
| 01h | bDescriptorType | 1 | 05h | No | Endpoint Descriptor |
| 02h | bEndpointAddress | 1 | 81h | No | Endpoint Address |
| 03h | bmAttributes | 1 | 02h | No | Bulk Transfer Type |
| 04h | wMaxPacketSize | 2 | Note 5-9 | No | Maximum Packet Size this endpoint is capable of sending. |
| 06h | blInterval | 1 | 00h | No | Interval for polling endpoint data transfers. Ignored for bulk endpoints. |

Note 5-9 64 bytes for Full-Speed mode. 512 bytes for Hi-Speed mode.

5.3.1.6.5 Endpoint 2 (Bulk Out) Descriptor

Table 5-8 shows the default value for Endpoint Descriptor 2. This descriptor is not initialized from values stored in EEPROM.

TABLE 5-8: ENDPOINT 2 DESCRIPTOR

| Offset | Field | Size (Bytes) | Default Value | Loaded from EEPROM | Description |
|--------|------------------|--------------|---------------|--------------------|---|
| 00h | bLength | 1 | 07h | No | Size of Descriptor in bytes |
| 01h | bDescriptorType | 1 | 05h | No | Endpoint Descriptor |
| 02h | bEndpointAddress | 1 | 02h | No | Endpoint Address |
| 03h | bmAttributes | 1 | 02h | No | Bulk Transfer Type |
| 04h | wMaxPacketSize | 2 | Note 5-10 | No | Maximum Packet Size this endpoint is capable of sending. |
| 06h | blInterval | 1 | 00h | No | Interval for polling endpoint data transfers. Ignored for bulk endpoints. |

Note 5-10 64 bytes for Full-Speed mode. 512 bytes for Hi-Speed mode.

5.3.1.6.6 Endpoint 3 (Interrupt) Descriptor

Table 5-9 shows the default value for Endpoint Descriptor 3. Only the blInterval field of this descriptor is initialized from EEPROM.

TABLE 5-9: ENDPOINT 3 DESCRIPTOR

| Offset | Field | Size (Bytes) | Default Value | Loaded from EEPROM | Description |
|--------|------------------|--------------|---------------|--------------------|-----------------------------|
| 00h | bLength | 1 | 07h | No | Size of Descriptor in bytes |
| 01h | bDescriptorType | 1 | 05h | No | Endpoint Descriptor |
| 02h | bEndpointAddress | 1 | 83h | No | Endpoint Address |
| 03h | bmAttributes | 1 | 03h | No | Interrupt Transfer Type |

LAN950x

TABLE 5-9: ENDPOINT 3 DESCRIPTOR (CONTINUED)

| Offset | Field | Size (Bytes) | Default Value | Loaded from EEPROM | Description |
|--------|----------------|--------------|---------------|--------------------|--|
| 04h | wMaxPacketSize | 2 | 10h | No | Maximum Packet Size this endpoint is capable of sending. |
| 06h | bInterval | 1 | Note 5-11 | Yes | Interval for polling endpoint data transfers. |

Note 5-11 This value is loaded from the EEPROM. A Full-Speed and Hi-Speed polling interval exists. If no EEPROM exists than this value defaults to 04h for HS and 01h for FS.

5.3.1.6.7 Other Speed Configuration Descriptor

The fields in this descriptor are derived from Configuration Descriptor information that is stored in the EEPROM.

TABLE 5-10: OTHER SPEED CONFIGURATION DESCRIPTOR

| Offset | Field | Size (Bytes) | Default Value | Loaded from EEPROM | Description |
|--------|---------------------|--------------|---------------|--------------------|--|
| 00h | bLength | 1 | 09h | Note 5-12 | Size of Descriptor in bytes (9 bytes) |
| 01h | bDescriptorType | 1 | 07h | Note 5-12 | Other Speed Configuration Descriptor (0x07) |
| 02h | wTotalLength | 2 | 0027h | Note 5-12 | Total length in bytes of data returned (39 bytes) |
| 04h | bNumInterfaces | 1 | 01h | Note 5-12 | Number of Interfaces |
| 05h | bConfigurationValue | 1 | 01h | Note 5-12 | Value to use as an argument to select this configuration |
| 06h | iConfiguration | 1 | 00h | Yes | Index of String Descriptor describing this configuration |
| 07h | bmAttributes | 1 | A0h | Yes | Bus powered and remote wakeup enabled. |
| 08h | bMaxPower | 1 | Note 5-13 | Yes | Maximum Power Consumption is 500 mA. |

Note: EEPROM values are obtained for the Configuration Descriptor at the other USB speed. I.e., if the current operating speed is FS, then the HS Configuration Descriptor values are used, and vice-versa.

Note 5-12 Value is loaded from EEPROM, but must be equal to the Default Value in order to comply with the USB 2.0 Specification and provide for normal device operation. Specification of any other value will result in unwanted behavior and untoward operation.

Note 5-13 Default value is 01h in Self Powered mode and FAh in Bus Powered mode.

Note: The PWR_SEL and RMT_WKP straps affect the default value of bmAttributes.

5.3.1.6.8 Device Qualifier Descriptor

The fields in this descriptor are derived from Device Descriptor information that is stored in the EEPROM.

TABLE 5-11: DEVICE QUALIFIER DESCRIPTOR

| Offset | Field | Size (Bytes) | Default Value | Loaded from EEPROM | Description |
|--------|--------------------|--------------|---------------|--------------------|--|
| 00h | bLength | 1 | 0Ah | No | Size of Descriptor in bytes (10 bytes) |
| 01h | bDescriptorType | 1 | 06h | No | Device Qualifier Descriptor (0x06) |
| 02h | bcdUSB | 2 | 0200h | Note 5-14 | USB Specification Number which device complies to. |
| 04h | bDeviceClass | 1 | FFh | Yes | Class Code |
| 05h | bDeviceSubClass | 1 | 00h | Yes | Subclass Code |
| 06h | bDeviceProtocol | 1 | FFh | Yes | Protocol Code |
| 07h | bMaxPacketSize0 | 1 | 40h | Note 5-14 | Maximum Packet Size |
| 08h | bNumConfigurations | 1 | 01h | Note 5-14 | Number of Other-Speed Configurations |
| 09h | Reserved | 1 | 00h | No | Must be zero |

Note: EEPROM values are from the Device Descriptor (including any EEPROM override) at the opposite HS/FS operating speed. I.e., if the current operating speed is HS, then Device Qualifier data is based on the FS Device Descriptor, and vice-versa.

Note 5-14 Value is loaded from EEPROM, but must be equal to the Default Value in order to comply with the USB 2.0 Specification and provide for normal device operation. Specification of any other value will result in unwanted behavior and untoward operation.

5.3.1.6.9 String Descriptors

String Index = 0 (LANGID)

TABLE 5-12: LANGID STRING DESCRIPTOR

| Offset | Field | Size (Bytes) | Default Value | Loaded from EEPROM | Description |
|--------|-----------------|--------------|---------------|--------------------|--|
| 00h | bLength | 1 | 04h | No | Size of LANGID Descriptor in bytes (4 bytes) |
| 01h | bDescriptorType | 1 | 03h | No | String Descriptor (0x03) |
| 02h | LANGID | 2 | None | Yes | Must be set to 0x0409 (US English). |

Note 1: If there is no valid/enabled EEPROM, or if all string lengths in the EEPROM are 0, then there are no strings, so any host attempt to read the LANGID string will return stall in the Data Stage of the Control Transfer.

If there is a valid/enabled EEPROM, and if at least one of the string lengths in the EEPROM is not 0, then the value contained at EEPROM addresses 0x0A-0x0B will be returned. These must be 0x0409 to allow for proper device operation.

- 2: The device ignores the LANGID field in Control Read's of Strings, and will not return the String (if it exists), regardless of whether the requested LANGID is 0x0409 or not.

LAN950x

String Indices 1-5

TABLE 5-13: STRING DESCRIPTOR (INDICES 1-5)

| Offset | Field | Size (Bytes) | Default Value | Loaded from EEPROM | Description |
|--------|-----------------|--------------|---------------|--------------------|--|
| 00h | bLength | 1 | none | Yes | Size of the String Descriptor in bytes (4 bytes) |
| 01h | bDescriptorType | 1 | none | Yes | String Descriptor (0x03) |
| 02h | Unicode String | 2*N | none | Yes | 2 bytes per unicode character, no trailing NULL. |

Note 1: If there is no valid/enabled EEPROM, or if the corresponding String Length and offset in the EEPROM for a give string index are zero, then that string does not exist, so any host attempt to read that string will return stall in the Data Stage of the Control Transfer.

2: The device returns whatever bytes are in the designated EEPROM area for each of these strings it is the responsibility of the EEPROM programmer to correctly set the bLength and bDescriptorType fields in the descriptor consistent with the byte length specified in the corresponding EEPROM locations.

5.3.1.7 Statistics

The CTL tracks the statistics listed in [Table 5-14](#). The statistics are read via the Get Statistics Vendor Command.

Note: (LAN9500/LAN9500i ONLY):

The counters do not rollover and they are cleared on read.

(LAN9500A/LAN9500Ai ONLY):

The counters are snapshot when fulfilling the command request. The statistics counters rollover.

Error conditions are indicated via the RX Status Word, [Table 5-40 on page 45](#), or the TX Status Word, [Table 5-44 on page 50](#).

TABLE 5-14: STATISTICS COUNTERS

| Name | Description | Size (Bits) |
|--------------------------|---|-------------|
| RX Good Frames | Number of good RX frames received. Includes frames dropped by the FCT. | 32 |
| RX CRC Errors | Number of RX frames received with CRC-32 errors. Note: A CRC error is indicated when the CRC error flag is set and the dribbling bit flag is not set. | 20 |
| RX Runt Frame Errors | Number of RX frames received with a length of less than 64 bytes and a CRC error. | 20 |
| RX Alignment Errors | Number of RX frames received with alignment errors. Note: An alignment error is indicated by the presence of the CRC error flag is set and the dribbling bit flag is set. | 20 |
| RX Frame Too Long Error | Number of RX frames received with a length greater than the programmed maximum Ethernet frame size. | 20 |
| RX Later Collision Error | Number of RX frames received where a late collision has occurred. | 20 |
| RX Bad Frames | Total number of errored Ethernet frames received. This counter does not include RX FIFO Dropped Frames. | 20 |
| RX FIFO Dropped Frames | Number of RX frames dropped by the FCT due to insufficient room in the RX FIFO. Note: If an RX FIFO dropped frame has an Ethernet error, i.e CRC error, it must only be counted by the RX FIFO Dropped Frames counters. | 20 |

TABLE 5-14: STATISTICS COUNTERS (CONTINUED)

| Name | Description | Size (Bits) |
|-------------------------------|---|-------------|
| TX Good Frames | Number of successfully transmitted TX frames. Note: Does not count pause frames. | 32 |
| TX Pause Frames | Number of successfully transmitted pause frames. | 20 |
| TX Single Collisions | Number of successfully transmitted frames with one collision. | 20 |
| TX Multiple Collisions | Number of successfully transmitted frames with more than one collision. | 20 |
| TX Excessive Collision Errors | Number of transmitted frames aborted due to excessive collisions. | 20 |
| TX Late Collision Errors | Number of transmitted frames aborted due to late collisions. | 20 |
| TX Buffer Underrun Errors | Number of transmitted frames aborted due to Tx buffer under run. | 20 |
| TX Excessive Deferral Errors | Number of transmitted frames aborted due to excessive deferrals. | 20 |
| TX Carrier Errors | Number of frames transmitted in which the carrier signal was lost or in which the carrier signal was not present. | 20 |
| TX Bad Frames | Total number of errored Ethernet frames transmitted. | 20 |

5.3.2 USB STANDARD COMMANDS

This section lists the formats of the supported USB Standard Commands. The Set Descriptor, Set Interface, and Synchron Frame commands are not supported.

5.3.2.1 Clear Feature

This command clears the Stall status of the targeted endpoint or the device remote wakeup.

TABLE 5-15: FORMAT OF CLEAR FEATURE SETUP STAGE

| Offset | Field | Value |
|--------|---------------|---------------------------|
| 0h | bmRequestType | Note 5-15 |
| 1h | bRequest | 01h |
| 2h | wValue | Selects feature to clear. |
| 4h | wIndex | Note 5-16 |
| 6h | wLength | 00h |

Note 5-15 Set to 00h to clear device remote wakeup event. Set to 02h to clear the endpoint stall status.

Note 5-16 When the bmRequestType field specifies an endpoint, the wIndex field selects the endpoint (0, 1, 2, or 3) targeted by the command.

5.3.2.2 Get Configuration

TABLE 5-16: FORMAT OF CLEAR FEATURE SETUP STAGE

| Offset | Field | Value |
|--------|---------------|-------|
| 0h | bmRequestType | 80h |
| 1h | bRequest | 08h |
| 2h | wValue | 00h |
| 4h | wIndex | 00h |
| 6h | wLength | 01h |

LAN950x

TABLE 5-17: FORMAT OF GET CONFIGURATION DATA STAGE

| Offset | Field |
|--------|-----------------------------|
| 0h | Returns bConfigurationValue |

5.3.2.3 Get Descriptor

TABLE 5-18: FORMAT FOR GET DESCRIPTOR SETUP STAGE

| Offset | Field | Value |
|--------|---------------|----------------------|
| 0h | bmRequestType | 80h |
| 1h | bRequest | 06h |
| 2h | wValue | Note 5-17 |
| 4h | wIndex | Note 5-18 |
| 6h | wLength | Length of descriptor |

Note 5-17 Selects descriptor type. The support descriptors for this command are Device, Configuration, String, Device Qualifier, and Other Speed Configuration.

Note 5-18 Set to zero or Language ID.

Note: The Interface and Endpoint descriptors are not supported by this command. The UDC will stall these requests.

5.3.2.4 Get Interface

TABLE 5-19: FORMAT OF GET INTERFACE SETUP STAGE

| Offset | Field | Value |
|--------|---------------|-------|
| 0h | bmRequestType | 81h |
| 1h | bRequest | 0Ah |
| 2h | wValue | 00h |
| 4h | wIndex | 00h |
| 6h | wLength | 01h |

TABLE 5-20: GET INTERFACE DATA STAGE

| Offset | Field |
|--------|-------------------|
| 0h | Alternate Setting |

Note: The device only supports a single interface.

5.3.2.5 Get Status

5.3.2.5.1 Device Status

TABLE 5-21: FORMAT OF GET STATUS (DEVICE) SETUP STAGE

| Offset | Field | Value |
|--------|---------------|-------|
| 0h | bmRequestType | 80h |
| 1h | bRequest | 00h |
| 2h | wValue | 00h |
| 4h | wIndex | 00h |
| 6h | wLength | 02h |

TABLE 5-22: FORMAT OF GET STATUS (DEVICE) DATA STAGE

| Offset | Field |
|--------|---|
| 0h | {00h, 0h, 00b, Remote Wakeup, Self Powered} |

5.3.2.5.2 Endpoint 1 Status (Bulk In)

TABLE 5-23: FORMAT OF GET STATUS (ENDPOINT 1) SETUP STAGE

| Offset | Field | Value |
|--------|---------------|-------|
| 0h | bmRequestType | 82h |
| 1h | bRequest | 00h |
| 2h | wValue | 00h |
| 4h | wIndex | 81h |
| 6h | wLength | 02h |

TABLE 5-24: FORMAT OF GET STATUS (ENDPOINT 1) DATA STAGE

| Offset | Field |
|--------|-------------------------------|
| 0h | {00h, 0h, 000b, Stall status} |

5.3.2.5.3 Endpoint 2 Status (Bulk Out)

TABLE 5-25: FORMAT OF GET STATUS (ENDPOINT 2) SETUP STAGE

| Offset | Field | Value |
|--------|---------------|-------|
| 0h | bmRequestType | 82h |
| 1h | bRequest | 00h |
| 2h | wValue | 00h |
| 4h | wIndex | 02h |
| 6h | wLength | 02h |

TABLE 5-26: FORMAT OF GET STATUS (ENDPOINT 2) DATA STAGE

| Offset | Field |
|--------|-------------------------------|
| 0h | {00h, 0h, 000b, Stall status} |

LAN950x

5.3.2.5.4 Endpoint 3 Status (Interrupt)

TABLE 5-27: FORMAT OF GET STATUS (ENDPOINT 3) SETUP STAGE

| Offset | Field | Value |
|--------|---------------|-------|
| 0h | bmRequestType | 82h |
| 1h | bRequest | 00h |
| 2h | wValue | 00h |
| 4h | wIndex | 83h |
| 6h | wLength | 02h |

TABLE 5-28: FORMAT OF GET STATUS (ENDPOINT 3) DATA STAGE

| Offset | Field |
|--------|-------------------------------|
| 0h | {00h, 0h, 000b, Stall status} |

5.3.2.5.5 Set Address

TABLE 5-29: FORMAT OF SET ADDRESS SETUP STAGE

| Offset | Field | Value |
|--------|---------------|----------------|
| 0h | bmRequestType | 00h |
| 1h | bRequest | 05h |
| 2h | wValue | Device address |
| 4h | wIndex | 00h |
| 6h | wLength | 00h |

5.3.2.5.6 Set Feature

This command sets the Stall feature for all supported endpoints. It also supports the Device Remote Wakeup Feature and Test mode.

TABLE 5-30: FORMAT OF SET FEATURE SETUP STAGE

| Offset | Field | Value |
|--------|---------------|---|
| 0h | bmRequestType | <ul style="list-style-type: none">• 00h for device• 02h for endpoint |
| 1h | bRequest | 03h |
| 2h | wValue | <ul style="list-style-type: none">• 01h for DEVICE_REMOTE_WAKEUP• 00h for ENDPOINT_HALT• 02h for EST_MODE |
| 4h | wIndex | <ul style="list-style-type: none">• 00h for device remote wakeup• 00h for TEST_MODE• Interface endpoint number for halt |
| 6h | wLength | 00h |

5.3.2.5.7 Set Configuration

The device supports only one configuration. An occurrence of this command places the device into the Configured state.

TABLE 5-31: FORMAT OF SET CONFIGURATION SETUP STAGE

| Offset | Field | Value |
|--------|---------------|---------------------|
| 0h | bmRequestType | 00h |
| 1h | bRequest | 09h |
| 2h | wValue | Configuration Value |
| 4h | wIndex | 00h |
| 6h | wLength | 00h |

Since only one configuration is supported, 01h is the only supported configuration value.

5.3.2.5.8 Set Interface

Only one interface is supported by the device. Therefore, this command is of marginal use. If the command is issued with an alternative setting of 00h and interface setting of 00h, as shown in [Table 5-32](#), the device responds with an ACK. Otherwise it responds with a STALL handshake.

TABLE 5-32: FORMAT OF SET INTERFACE SETUP STAGE

| Offset | Field | Value |
|--------|---------------|-------|
| 0h | bmRequestType | 01h |
| 1h | bRequest | 0Bh |
| 2h | wValue | 00h |
| 4h | wIndex | 00h |
| 6h | wLength | 00h |

5.3.3 USB VENDOR COMMANDS

The device implements several vendor specific commands in order to access CSRs and efficiently gather statistics. The vendor commands allow direct access to Systems CSRs and MAC CSRs.

Note: When in the Normal state, accesses to the MAC CSRs are stalled.

5.3.3.1 Register Write Command

The commands allows the Host to write a single register. Burst writes are not supported. All writes are 32-bits.

TABLE 5-33: FORMAT OF REGISTER WRITE SETUP STAGE

| Offset | Field | Value |
|--------|---------------|-------------------------|
| 0h | bmRequestType | 40h |
| 1h | bRequest | A0h |
| 2h | wValue | 00h |
| 4h | wIndex | {0h, CSR Address[11:0]} |
| 6h | wLength | 04h |

TABLE 5-34: FORMAT OF REGISTER WRITE DATA STAGE

| Offset | Field |
|--------|----------------------------|
| 0h | Register Write Data [31:0] |

LAN950x

5.3.3.2 Register Read Command

The commands allows the Host to read a single register. Burst reads are not supported. All reads return 32-bits.

TABLE 5-35: FORMAT OF REGISTER READ SETUP STAGE

| Offset | Field | Value |
|--------|---------------|-------------------------|
| 0h | bmRequestType | C0h |
| 1h | bRequest | A1h |
| 2h | wValue | 00h |
| 4h | wIndex | {0h, CSR Address[11:0]} |
| 6h | wLength | 04h |

TABLE 5-36: FORMAT OF REGISTER READ DATA STAGE

| Offset | Field |
|--------|---------------------------|
| 0h | Register Read Data [31:0] |

5.3.3.3 Get Statistics Command

The Get Statistics Command returns the entire contents of the statistics RAMs. The wIndex field is used to select the RX or TX statistics.

Note: (LAN9500/LAN9500i ONLY):

The contents of the statistics RAM is cleared after the command is processed.

(LAN9500A/LAN9500Ai ONLY):

The contents of the statistics RAM is snapshot when fulfilling the command request. The statistics counters rollover, hence the RAM is not cleared.

TABLE 5-37: FORMAT OF GET STATISTICS SETUP STAGE

| Offset | Field | Value |
|--------|---------------|---------------------------|
| 0h | bmRequestType | C0h |
| 1h | bRequest | A2h |
| 2h | wValue | 00h |
| 4h | wIndex | Note 5-19 |
| 6h | wLength | Note 5-20 |

Note 5-19 0b - Retrieves RX statistics. 1b - Retrieves TX statistics.

Note 5-20 20h for RX statistics. 28h for TX statistics.

TABLE 5-38: FORMAT OF GET STATISTICS DATA STAGE (RX)

| Offset | Field |
|--------|--------------------------|
| 00h | RX Good Frames |
| 04h | RX CRC Errors |
| 08h | RX Runt Frame Errors |
| 0Ch | RX Alignment Errors |
| 10h | RX Frame Too Long Error |
| 14h | RX Later Collision Error |
| 18h | RX Bad Frames |
| 1Ch | RX FIFO Dropped Frames |

TABLE 5-39: FORMAT OF GET STATISTICS DATA STAGE (TX)

| Offset | Field |
|--------|-------------------------------|
| 00h | TX Good Frames |
| 04h | TX Pause Frames |
| 08h | TX Single Collisions |
| 0Ch | TX Multiple Collisions |
| 10h | TX Excessive Collision Errors |
| 14h | TX Late Collision Errors |
| 18h | TX Buffer Underrun Errors |
| 1Ch | TX Excessive Deferral Errors |
| 20h | TX Carrier Errors |
| 24h | TX Bad Frames |

5.4 FIFO Controller (FCT)

The FIFO controller uses a 28 KB internal SRAM to buffer RX and TX traffic. 20 KB is allocated for received Ethernet-USB traffic (RX buffer), while 8 KB is allocated for USB-Ethernet traffic (TX buffer). Bulk-Out packets from the USB controller are directly stored into the TX buffer. The FCT is responsible for extracting Ethernet frames from the USB packet data and passing the frames to the MAC. Ethernet Frames are directly stored into the RX buffer and become the basis for bulk-in packets. The FCT passes the stored data to the UTX in blocks typically 512 or 64 bytes in size, depending on the current HS/FS USB operating speed.

5.4.1 RX PATH (ETHERNET -> USB)

The 20 KB RX FIFO buffers Ethernet frames received from the TLI. The UTX extracts these frames from the FCT to form USB Bulk In packets. The Host drivers will ultimately reassemble the Ethernet frames from the USB packets.

The FCT manages the writing of data into the RX FIFO through the use of two pointers - the `rx_wr_ptr` and the `rx_wr_hd_ptr`. The `rx_wr_ptr` is used to write Ethernet frame data into the FIFO. The `rx_wr_hd_ptr` points to the location prior to the first DWORD of the frame. It is used to write the RX Status Word received from the TLI, upon completion of a frame transaction. This status word contains status information associated with the frame and the frame transaction. [Figure 5-4](#) illustrates how a frame is stored in the FIFO, along with pointer usage.

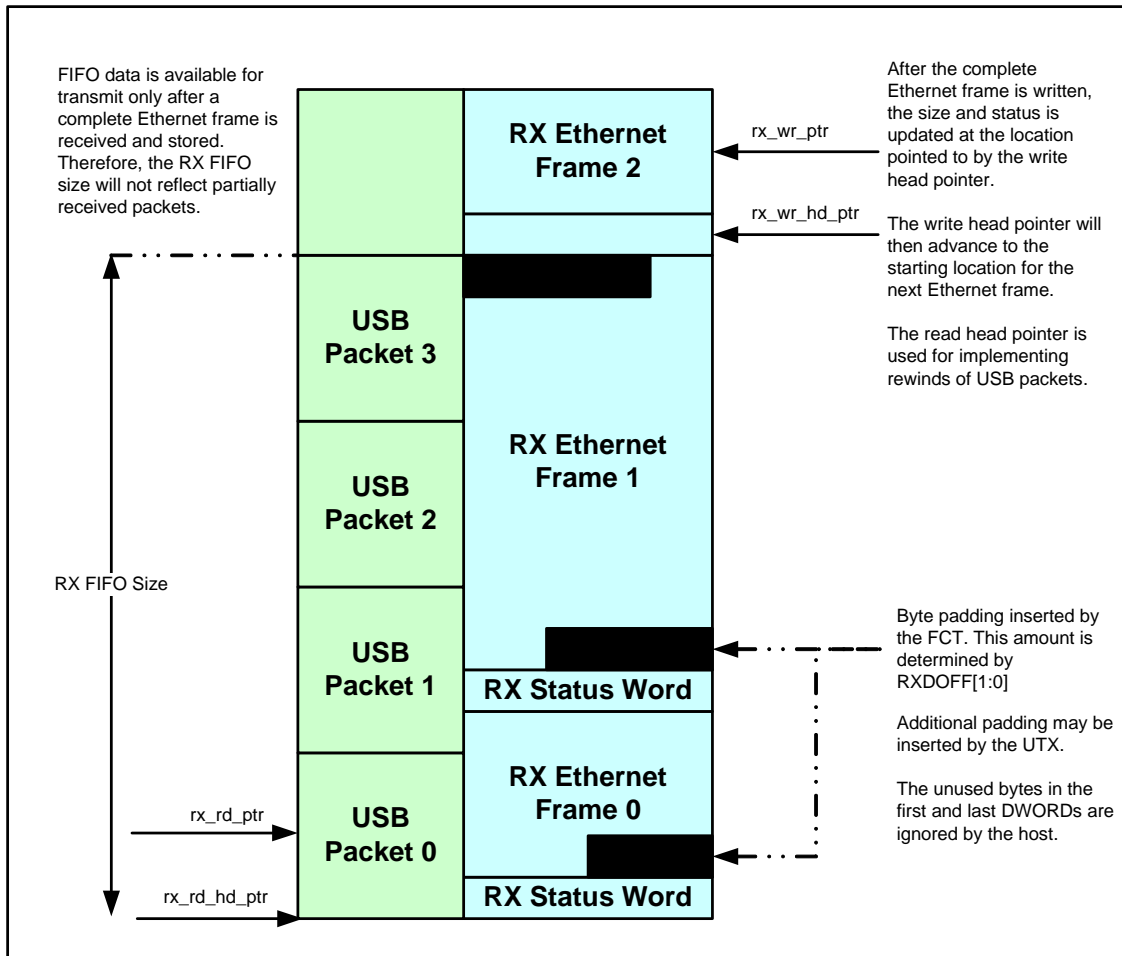

When the RX TLI signals that it has Data ready, the RX TLI controller starts passing the RX packet data to the FCT. The FCT updates the RX FIFO pointers as the data is written into the FIFO. The last transfer from the TLI is the RX Status Word.

The FCT may insert 0 - 3 bytes at the start of the Ethernet frame. The value of the [RX Data Offset \(RXDOFF\)](#) field of the [Hardware Configuration Register \(HW_CFG\)](#) on [page 122](#) determines the number of bytes inserted.

LAN950x

A received Ethernet frame is not visible to the UTX until the complete frame, including the RX Status Word, has been written into the RX FIFO. This is due to the fact that the frame may have to be removed via a rewind (pointer adjustment), in case of an error. Such is the case when a FIFO overflow condition is detected as the frame is being received. The FCT may also be configured to rewind errored frames. Please refer to [Section 5.4.1.1, "RX Error Detection," on page 44](#) for further details.

FIGURE 5-4: RX FIFO STORAGE

5.4.1.1 RX Error Detection

The FCT can be configured to drop Ethernet frames when certain error conditions occur. The setting of the [Discard Errored Received Ethernet Frame \(DRP\)](#) bit of the [Hardware Configuration Register \(HW_CFG\)](#) on page 122 determines if the frame will be retained or dropped. Error conditions are indicated in the Rx Status Word. The following error conditions are tracked by the TLI:

- CRC Error
- Collision Seen
- Frame Too Long
- Runt Frame

Please refer to [Section 5.3.1.7, "Statistics," on page 36](#) for more details on the error conditions tracked by the device.

The FCT also drops frames when it detects a FIFO overflow condition. This occurs when the FIFO full condition occurs while a frame is being received. The FCT also maintains a count of the number of times a FIFO overflow condition has occurred.

Dropping an Ethernet frame is implemented by rewinding the received frame. A write side rewind is implemented by setting the rx_wr_ptr to be equal to the rx_wr_hd_ptr. Similarly, a read side rewind is implemented by setting the rx_rd_ptr to be equal to the rx_rd_hd_ptr.

For the case where the frame is dropped due to overflow, the FCT ignores the remainder of the frame. It will not begin writing into the RX FIFO again until the next frame is received.

In the read direction, the FCT must also support rewinds for the UTX. This is needed for the case where the USB Bulk Out packet is not successfully received by the Host and needs to be retransmitted.

5.4.1.2 RX Status Format

Table 5-40 illustrates the format of the RX Status Word.

TABLE 5-40: RX STATUS WORD FORMAT

| Bits | Description |
|-------|--|
| 31 | RESERVED |
| 30 | Filtering Fail When set, this bit indicates that the associated frame failed the address recognizing filtering. |
| 29:16 | Frame Length The size, in bytes, of the corresponding received frame. |
| 15 | Error Status (ES) When set, this bit indicates that the TLI has reported an error. This bit is the logical OR of bits 11, 7, 6, 1 in this status word. |
| 14 | RESERVED |
| 13 | Broadcast Frame When set, this bit indicates that the received frame has a Broadcast address. |
| 12 | Length Error (LE) When set, this bit indicates that the actual length does not match with the length/type field of the received frame. |
| 11 | Runt Frame When set, this bit indicates that frame was prematurely terminated before the collision window (64 bytes). Runt frames are passed on to the Host only if the Pass Bad Frames bit MAC_CR Bit [16] is set. |
| 10 | Multicast Frame When set, this bit indicates that the received frame has a Multicast address. |
| 9:8 | RESERVED |
| 7 | Frame Too Long When set, this bit indicates that the frame length exceeds the maximum Ethernet specification of 1518 bytes. This is only a frame too long indication and will not cause the frame reception to be truncated. |
| 6 | Collision Seen When set, this bit indicates that the frame has seen a collision after the collision window. This indicates that a late collision has occurred. |
| 5 | Frame Type When set, this bit indicates that the frame is an Ethernet-type frame (Length/Type field in the frame is greater than 1500). When reset, it indicates the incoming frame was an 802.3 type frame. This bit is not set for Runt frames less than 14 bytes. |
| 4 | Receive Watchdog time-out When set, this bit indicates that the incoming frame is greater than 2048 bytes through 2560 bytes, therefore expiring the Receive Watchdog Timer. |
| 3 | MII Error When set, this bit indicates that a receive error (RX_ER asserted) was detected during frame reception. |
| 2 | Dribbling Bit When set, this bit indicates that the frame contained a no-integer multiple of 8 bits. This error is reported only if the number of dribbling bits in the last byte is 4 in the MII operating mode, or at least 3 in the 10 Mbps operating mode. This bit will not be set when the Collision Seen bit[6] is set. If set and the CRC error[1] bit is reset, then the frame is considered to be valid. |

TABLE 5-40: RX STATUS WORD FORMAT (CONTINUED)

| Bits | Description |
|------|--|
| 1 | CRC Error When set, this bit indicates that a CRC error was detected. This bit is also set when the RX_ER pin is asserted during the reception of a frame even though the CRC may be correct. This bit is not valid if the received frame is a Runt frame, or a late collision was detected or when the Watchdog Timeout occurs. |
| 0 | RESERVED |

5.4.1.3 Flushing the RX FIFO

The device allows for the Host to flush the entire contents of the FCT RX FIFO. When a flush is activated, the read and write pointers of the RX FIFO are returned to their reset state.

Before flushing the RX FIFO, the device's receiver must be stopped, as specified in [Section 5.4.1.4](#). Once the receiver stop completion is confirmed, the [Receive FIFO Flush](#) bit can be set in the [Receive Configuration Register \(RX_CFG\)](#) on [page 120](#) to initiate the flush operation. This bit is cleared after the flush is complete.

5.4.1.4 Stopping and Starting the Receiver

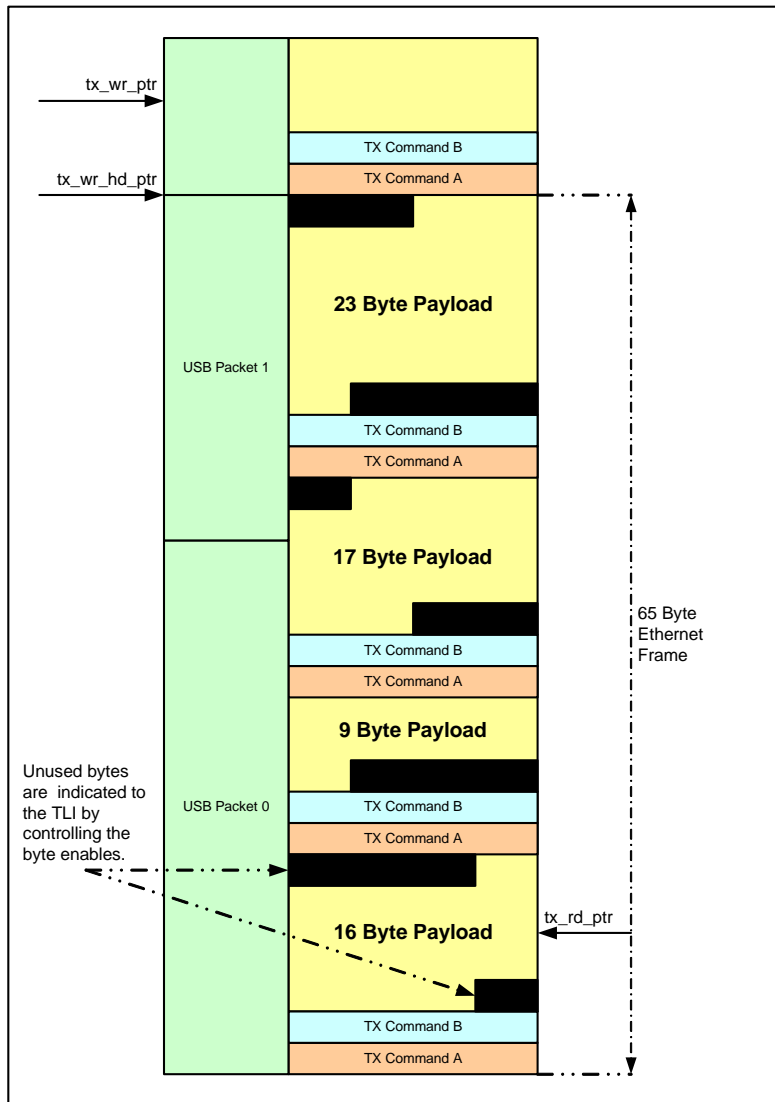

To stop the receiver, the Host must clear the [Receiver Enable \(RXEN\)](#) bit in the [MAC Control Register \(MAC_CR\)](#) on [page 159](#). When the receiver is halted, the RXSTOP_INT will be pulsed. Once stopped, the Host can optionally clear the RX Status and RX FIFOs. The Host must re-enable the receiver by setting the RXEN bit.

5.4.2 TX PATH (USB -> ETHERNET)

The 8 KB TX FIFO buffers USB Bulk Out packets received by the URX. The FCT is responsible for extracting the Ethernet frames embedded in the USB Bulk Out Packets and passing them to the TLI. The Ethernet frames were segmented across the USB packets by the Host drivers.

The FCT manages the writing of data into the TX FIFO through the use of two pointers - the tx_wr_ptr and the tx_wr_hd_ptr. These pointers are used to manage the storing of USB Bulk Out packets. They support rewinding the stored USB packet, in the event that the Bulk Out Packet is errored and needs to be retransmitted by the Host. The write side of the FCT does not perform any processing on the USB packet data. The read side of the TX FIFO is responsible for extracting the Ethernet frames. The Ethernet frames may be split across multiple buffers, as shown in [Figure 5-5](#).

FIGURE 5-5: TX FIFO STORAGE

5.4.2.1 TX Command Format

As shown in [Figure 5-5](#), each buffer starts with a two DWORD TX Command. The TX Command instructs the FCT on the handling of the associated buffer. The command precedes the data to be transmitted. The TX command is divided into two, 32-bit words; TX Command A and TX command B.

Both TX command A and TX command B are required for each buffer in a given packet. TX command B must be identical for every buffer in a given packet, with the exception of the [TX Checksum Enable \(CK\)](#) bit. If the TX command B DWORDs do not match, the FCT will assert the Transmitter Error (TXE) flag.

Frame boundaries are delineated using control bits within the TX command. The Frame Length field in TX Command B specifies the number of bytes in the associated frame. All Frame Length fields must have the same value for all buffers in a given Frame. Hardware compares the Frame Length field and the actual amount of data received. If the actual frame length count does not match the Frame Length field, an error has occurred.

The formats of TX Command A and TX Command B are shown in [Table 5-41](#) and [Table 5-42](#), respectively.

LAN950x

TABLE 5-41: TX COMMAND A FORMAT

| BITS | DESCRIPTION |
|-------|--|
| 31:18 | RESERVED |
| 17:16 | Data Start Offset (bytes) This field specifies the offset of the first byte of TX Data. The offset value ranges between 0 bytes and 3 bytes. |
| 15:14 | RESERVED |
| 13 | First Segment When set, this bit indicates that the associated buffer is the first segment of the frame. |
| 12 | Last Segment When set, this bit indicates that the associated buffer is the last segment of the frame. |
| 11 | RESERVED |
| 10:0 | Buffer Size (bytes) This field indicates the number of bytes contained in the buffer following the two command DWORDS (TX Command A and TX Command B). This value, along with the Data Start Offset field, is used by the FCT to determine how many extra bytes were added to the end of the Buffer. A running count is also maintained in the FCT of the cumulative buffer sizes for a given frame. This cumulative value is compared against the Frame Length field in the TX Command B word and if they do not correlate, the TXE flag is set. The buffer size specified does not include bytes added due to the end of buffer alignment padding or the Data Start Offset field. |

TABLE 5-42: TX COMMAND B FORMAT

| BITS | DESCRIPTION |
|-------|---|
| 31:15 | RESERVED |
| 14 | TX Checksum Enable (CK) If this bit is set in conjunction with the first segment bit (FS) in TX Command 'A' and the TX checksum offload engine enable bit (TXCOE_EN) in the checksum offload engine control register (COE_CR), the TX checksum offload engine (TXCOE) will calculate an L3 checksum for the associated frame. Note: This bit only needs to be set for the first buffer of a frame. |
| 13 | Add CRC Disable When set, the automatic addition of the CRC is disabled. |
| 12 | Disable Ethernet Frame Padding When set, this bit prevents the automatic addition of padding to an Ethernet frame of less than 64 bytes. The CRC field is also added despite the state of the Add CRC Disable field. |
| 11 | RESERVED |
| 10:0 | Frame Length (bytes) This field indicates the total number of bytes in the current frame. This length does not include the offset or padding. If the Frame Length field does not match the actual number of bytes in the frame, the Transmitter Error (TXE) flag will be set (in the Interrupt Status Register (INT_STS) and the interrupt endpoint). This value is read by the TX FIFO controller, and is used to determine the amount of data that must be moved from the TX data FIFO into the TLI block. If the byte count is not aligned to a DWORD boundary, the TX FIFO Controller will issue the correct byte enables to the TLI layer during the last write. Invalid bytes in the last DWORD will not be passed to the TLI for transmission. |

5.4.2.2 TX Data Format

The TX data section begins at the third DWORD in the TX buffer (after TX Command A and TX Command B). The location of the first byte of valid buffer data to be transmitted is specified in the Data Start Offset field of TX Command A. [Table 5-43, "TX Data Start Offset"](#) shows the correlation between the setting of the Lab's in the Data Start Offset field and the byte location of the first valid data byte.

TABLE 5-43: TX DATA START OFFSET

| Data Start Offset[1:0] | 11 | 10 | 01 | 00 |
|------------------------|----------|----------|---------|--------|
| First TX Data Byte | D[31:24] | D[23:16] | D[15:8] | D[7:0] |

TX data is contiguous until the end of the buffer. The buffer may end on a byte boundary. Unused bytes at the end of the packet will not be sent to the TLI for transmission.

5.4.2.3 TX Buffer Fragmentation Rules

Transmit buffers must adhere to the following rules:

- Each buffer may start and end on any arbitrary byte alignment.
- The first buffer of any transmit packet can be any length.
- Middle buffers (i.e., those with First Segment = Last Segment = 0) must be greater than, or equal to 4 bytes in length.
- The final buffer of any transmit packet can be any length.

5.4.2.4 FCT Actions

The FCT performs basic sanity checks on the correctness of the buffer configuration, as described in [Section 5.4.2.5, "TX Error Detection," on page 49](#). Errors in this regard indicate the TX path is out of sync, which is catastrophic and requires a reinitialization of the TX path.

The FCT performs the following steps when extracting an Ethernet frame:

- Strip out TX Command A
- Strip out TX Command B
- Account for the byte offset at the beginning of the frame. Based upon the buffer size and DataStartOffset[1:0] field of TX Command A, the FCT can numerically determine any unused bytes in the first and last word of the buffer. When transferring these respective DWORDs to the TLI, the FCT adjusts the byte enables accordingly.

Note: When a packet is split into multiple buffers, each successive buffer's data payload may begin on any arbitrary byte.

Unlike the write side, the read side of the TX FIFO does not need to support rewinds. Errors are reported via the Transmitter Error (TXE) flag, which is visible to the Host via the Interrupt Endpoint and is also set in the [Interrupt Status Register \(INT_STS\)](#).

5.4.2.5 TX Error Detection

As previously stated, both TX Command A and TX Command B are required for each buffer in a given frame. TX Command B must be identical for every buffer in a given frame, with the exception of the [TX Checksum Enable \(CK\)](#) bit. If the TX Command B words do not match, then the TX path is out of sync and the FCT asserts the Transmitter Error (TXE) flag.

Similarly, the FCT numerically adds up the size of the frame's buffers. If there is a numerical mismatch, the TX path is out of sync and the FCT asserts the Transmitter Error (TXE) flag. The following error conditions are tracked by the FCT:

- Missing FS - The expected first buffer of a frame does not have the FS bit set.
- Unexpected FS - The FS bit is set when the total size of buffers so far opened is less than the frame size.
- Missing LS - The total size of the buffers opened is equal to or exceeds the size of the frame. The FCT expects this buffer to have the LS bit set and it is not set.
- Unexpected LS - The LS bit is set when the aggregate total size of descriptor buffers so far opened is less than the frame size.

LAN950x

- Buffer Size is Zero Error - The buffer length field is zero.
- Buffer Size Error - The total sum of the buffers received is not equal to the frame length.

Note 1: The FCT can be configured to stall the Bulk Out pipe when a Transmit Error is detected. This is accomplished via the [Stall Bulk Out Pipe Disable \(SBP\)](#) bit of the [Hardware Configuration Register \(HW_CFG\)](#). Please refer to [Section 7.3.5, "Hardware Configuration Register \(HW_CFG\)," on page 122](#) for further details.

2: A TX Error is a catastrophic condition. The device should be reset in order to recover from it.

5.4.2.6 TX Status Format

After an Ethernet frame is transmitted, the TLI returns the TX Status Word to the FCT, as illustrated in [Table 5-44](#). The contents of the TX Status Word is used for statistics generation and interrupt status creation. Please refer to [Section 5.3.1.7, "Statistics," on page 36](#) and [Section 7.3.2, "Interrupt Status Register \(INT_STS\)"](#) for further details.

TABLE 5-44: TX STATUS WORD FORMAT

| Bits | Description |
|-------|--|
| 31:16 | RESERVED |
| 15 | Error Status (ES) When set, this bit indicates that the TLI has reported an error. This bit is the logical OR of bits 11, 10, 9, 8, 2, 1 in this status word. |
| 14:12 | RESERVED |
| 11 | Loss of Carrier When set, this bit indicates the loss of carrier during transmission. |
| 10 | No Carrier When set, this bit indicates that the carrier signal from the transceiver was not present during transmission. |
| 9 | Late Collision When set, indicates that the packet transmission was aborted after the collision window of 64 bytes. |
| 8 | Excessive Collisions When set, this bit indicates that the transmission was aborted after 16 collisions while attempting to transmit the current packet. |
| 7 | RESERVED |
| 6:3 | Collision Count This counter indicates the number of collisions that occurred before the packet was transmitted. It is not valid when excessive collisions (bit 8) is also set. |
| 2 | Excessive Deferral If the deferred bit is set in the control register, the setting of the excessive deferral bit indicates that the transmission has ended because of a deferral of over 24288 bit times during transmission. |
| 1 | Underrun Error When set, this bit indicates that the transmitter aborted the associated frame because of an underrun condition on the TX Data FIFO. TX Underrun will cause the assertion of the TDFU flag in the Interrupt Status Register (INT_STS) and the interrupt endpoint. |
| 0 | Deferred When set, this bit indicates that the current packet transmission was deferred. |

5.4.2.7 Transmit Examples

5.4.2.7.1 TX Example 1

In this example a single, 1064-Byte Ethernet frame will be transmitted. This packet is divided into three buffers. The three buffers are as follows:

Buffer 0:

- 3-Byte “Data Start Offset”
- 499-Bytes of payload data

Buffer 1:

- 0-Byte “Data Start Offset”
- 503-Bytes of payload data

Buffer 2:

- 2-Byte “Data Start Offset”
- 62-Bytes of payload data

[FIGURE 5-6: TX Example 1 on page 52](#) illustrates the TX command structure for this example, and also shows how data is passed to the TX data FIFO.

FIGURE 5-6: TX EXAMPLE 1

5.4.2.8 TX Example 2

In this example, a single 183-Byte Ethernet frame will be transmitted. This packet is in a single buffer as follows:

- 2-Byte “Data Start Offset”
- 183-Bytes of payload data

[FIGURE 5-7: TX Example 2 on page 53](#) illustrates the TX command structure for this example, and also shows how data is passed to the TX data FIFO. Note that the packet resides in a single TX Buffer, therefore both the FS and LS bits are set in TX Command A.

FIGURE 5-7: TX EXAMPLE 2

5.4.2.9 TX Example 3

In this example a single, 111-Byte Ethernet frame will be transmitted with a TX checksum. This packet is divided into four buffers. The four buffers are as follows:

Buffer 0:

- 0-Byte “Data Start Offset”
- 4-Byte Checksum Preamble

Buffer 1:

- 3-Byte “Data Start Offset”
- 79-Bytes of payload data

Buffer 2:

- 0-Byte “Data Start Offset”
- 15-Bytes of payload data

Buffer 3:

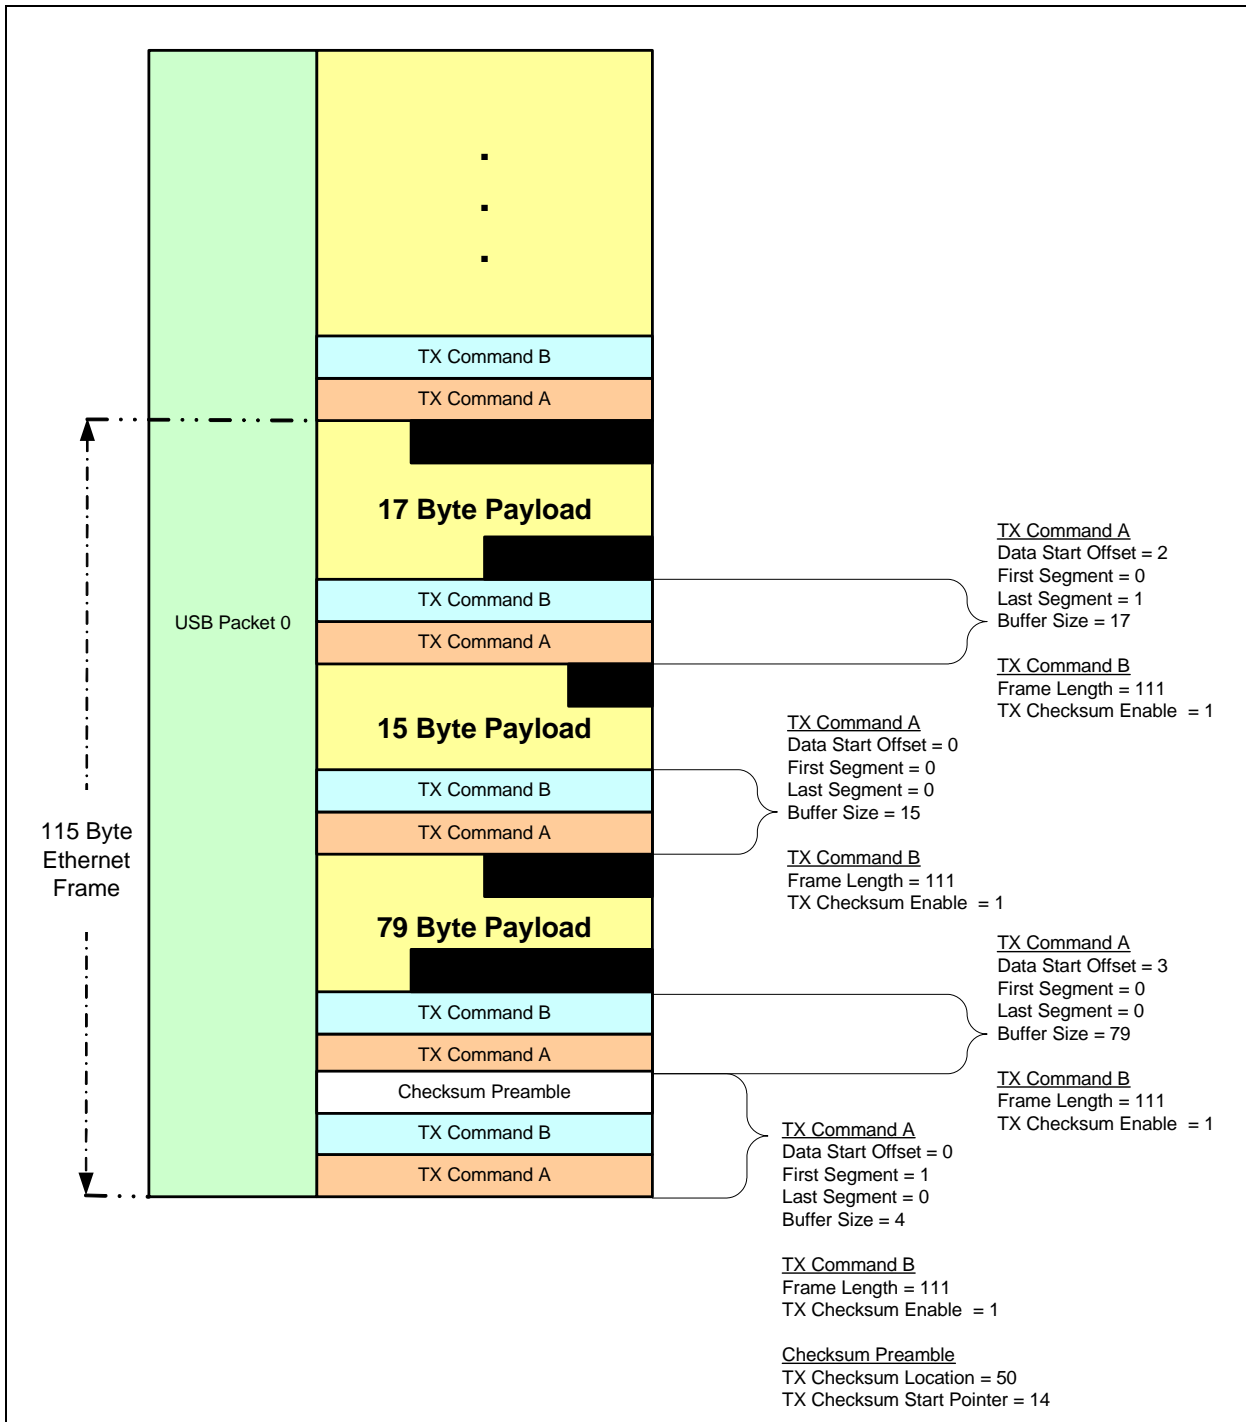

- 2-Byte “Data Start Offset”
- 17-Bytes of payload data

[FIGURE 5-8: TX Example 3 on page 54](#) illustrates the TX command structure for this example, and also shows how data is passed to the TX data FIFO.

LAN950x

Note: When enabled, the TX Checksum Preamble is pre-pended to the data to be transmitted. The FS bit in TX Command A, the TX Checksum Enable bit (CK) of TX Command B, and the TXCOE_EN bit of the COE_CR register must all be set for the TX checksum to be generated. FS must not be set for subsequent fragments of the same packet. Please refer to [Section 5.5.8, "Transmit Checksum Offload Engine \(TXCOE\)"](#) for further information.

FIGURE 5-8: TX EXAMPLE 3

5.4.2.10 Flushing the TX FIFO

The device allows for the Host to flush the entire contents of the FCT TX FIFO. When a flush is activated, the read and write pointers for the TX FIFO are returned to their reset state.

Before flushing the TX FIFO, the device's transmitter must be stopped, as specified in [Section 5.4.2.11](#). Once the transmitter stop completion is confirmed, the [Transmit FIFO Flush](#) bit can be set in the [Transmit Configuration Register \(TX_CFG\)](#) on [page 121](#). This bit is cleared after the flush is complete.

5.4.2.11 Stopping and Starting the Transmitter

To halt the transmitter, the Host must set the [Stop Transmitter \(STOP_TX\)](#) bit in the TX_CFG register. The transmitter will finish sending the current frame (if there is a frame transmission in progress). When the transmitter has received the TX Status for the current frame, it will clear the STOP_TX and TX_ON bits in the TX_CFG register, and will pulse TXSTOP_INT.

Once stopped, the Host can optionally flush the TX FIFO, and can optionally disable the MAC by clearing TXEN. The Host must re-enable the transmitter by setting the TX_ON and TXEN bits. If there are frames pending in the TX FIFO (i.e., the TX FIFO was not purged), the transmission will resume with this data.

Note: The TX Stop mechanism described here assumes that the MAC will return a status for every TX frame.

5.4.3 ARBITRATION

The FCT must arbitrate access to the RX and TX FIFOs to the URX, UTX, TLI RX, and TLI TX. Highest priority is always given to the USB. The TLI RX/TX can be wait stated as frames buffering exists in the TLI (2 KB TX, 128 Byte RX).

FCT strict priority order:

1. URX Request (Bulk Out Packet)
2. UTX Request (Bulk In Packet)
3. TLI RX (Received Ethernet Frame)
4. TLI TX (Transmitted Ethernet Frame)

Note: By nature of the USB bus and UDC operation, the URX and UTX should not request bandwidth simultaneously.

5.5 10/100 Ethernet MAC

The Ethernet Media Access controller (MAC) incorporates the essential protocol requirements for operating an Ethernet/IEEE 802.3-compliant node and provides an interface between the Host subsystem and the internal Ethernet PHY. The MAC can operate in either 100-Mbps or 10-Mbps mode.

The MAC operates in both half-duplex and full-duplex modes. When operating in half-duplex mode, the MAC complies fully with Section 4 of ISO/IEC 8802-3 (ANSI/IEEE standard) and ANSI/IEEE 802.3 standards. When operating in full-duplex mode, the MAC complies with IEEE 802.3x full-duplex operation standard.

The MAC provides programmable enhanced features designed to minimize Host supervision, bus utilization, and pre- or post-message processing. These features include the ability to disable retries after a collision, dynamic FCS (Frame Check Sequence) generation on a frame-by-frame basis, automatic pad field insertion and deletion to enforce minimum frame size attributes, layer 3 checksum calculation for transmit and receive operations, and automatic retransmission and detection of collision frames.

The MAC can sustain transmission or reception of minimally-sized back-to-back packets at full line speed with an inter-packet gap (IPG) of 9.6 microseconds for 10 Mbps and 0.96 microseconds for 100 Mbps.

The primary attributes of the MAC Function are:

- Transmit and receive message data encapsulation
- Framing (frame boundary delimitation, frame synchronization)
- Error detection (physical medium transmission errors)
- Media access management

LAN950x

- Medium allocation (collision detection, except in full-duplex operation)
- Contention resolution (collision handling, except in full-duplex operation)
- Flow control during full-duplex mode
- Decoding of control frames (PAUSE command) and disabling the transmitter
- Generation of control frames
- Interface to the internal PHY and optional external PHY.
- Checksum offload engine for calculation of layer 3 transmit and receive checksum.

The transmit and receive data paths are separate within the device from the MAC to Host interface, allowing the highest performance, especially in full duplex mode. Payload data as well as transmit and receive status are passed on these busses.

A third internal bus is used to access the MAC's "Control and Status Registers" (CSR's). This bus is also accessible from the Host.

On the backend, the MAC interfaces with the 10/100 PHY through an MII (Media Independent Interface) port which is internal to the device. In addition, there is an external MII interface supporting optional PHY devices. The MAC CSR's also provide a mechanism for accessing the PHY's internal registers through the internal SMI (Serial Management Interface) bus.

The receive and transmit FIFOs allow increased packet buffer storage to the MAC. The FIFOs are a conduit between the Host interface and the MAC through which all transmitted and received data and status information is passed. Deep FIFOs allow a high degree of latency tolerance relative to the various transport and OS software stacks reducing and minimizing overrun conditions. Like the MAC, the FIFOs have separate receive and transmit data paths.

5.5.1 FLOW CONTROL

The device's Ethernet MAC supports full-duplex flow control using the pause operation and control frame. It also supports half-duplex flow control using back pressure. In order for flow control to be invoked, the [Flow Control Enable \(FCEN\)](#) bit of the [Flow Control Register \(FLOW\)](#) must be set.

5.5.1.1 Full-Duplex Flow Control

The pause operation inhibits data transmission of data frames for a specified period of time. A Pause operation consists of a frame containing the globally assigned multicast address (01-80-C2-00-00-01), the PAUSE opcode, and a parameter indicating the quantum of slot time (512 bit times) to inhibit data transmissions. The PAUSE parameter may range from 0 to 65,535 slot times. The Ethernet MAC logic, on receiving a frame with the reserved multicast address and PAUSE opcode, inhibits data frame transmissions for the length of time indicated. If a Pause request is received while a transmission is in progress, then the pause will take effect after the transmission is complete. Control frames are received and processed by the MAC and are passed on.

The device will automatically transmit pause frames based on the settings of [Automatic Flow Control Configuration Register \(AFC_CFG\)](#) and the [Flow Control Register \(FLOW\)](#). When the RX FIFO reaches the level set in the [Automatic Flow Control High Level \(AFC_HI\)](#) field of AFC_CFG, the device will transmit a pause frame. The pause time field that is transmitted is set in the [Pause Time \(FCPT\)](#) field of the FLOW register. When the RX FIFO drops below the level set in the [Automatic Flow Control Low Level \(AFC_LO\)](#) field of AFC_CFG, the device will automatically transmit a pause frame with a pause time of zero. The device will only send another pause frame when the RX FIFO level falls below AFC_LO and then exceeds AFC_HI again.

5.5.1.2 Half-Duplex Flow Control (Backpressure)

In half-duplex mode, back pressure is used for flow control. Whenever the RX FIFO crosses a certain threshold level, the MAC starts sending a Jam signal. The MAC transmit logic enters a state at the end of current transmission (if any), where it waits for the beginning of a received frame. Once a new frame starts, the MAC starts sending the jam signal, which will result in a collision. After sensing the collision, the remote station will back off its transmission. The MAC continues sending the jam signal to make other stations defer transmission. The MAC only generates this collision-based back pressure when it receives a new frame, in order to avoid any late collisions.

The device will automatically assert back pressure based on the setting of the [Automatic Flow Control Configuration Register \(AFC_CFG\)](#). When the RX FIFO reaches the level set by [Automatic Flow Control High Level \(AFC_HI\)](#) field of AFC_CFG, the Back pressure Duration Timer will start. The device will assert back pressure for any received frames, as defined by the values of the FCANY, FCADD, FCMULT and FCBRD control bits of AFC_CFG. This continues until the Back pressure Duration Timer reaches the time specified by the BACK_DUR field of AFC_CFG. After the BACK_DUR time period has elapsed, the receiver will accept one frame. If, after receiving one RX frame, the RX FIFO

is still above the threshold set in the [Automatic Flow Control Low Level \(AFC_LO\)](#) field of AFC_CFG, the device will again start the Back pressure duration timer and will assert back pressure for subsequent frames, repeating the process described here until the RX Data FIFO level drops below the AFC_LO setting. If the RX FIFO drops below AFC_LO before the Back pressure Duration Timer has expired, the timer will immediately reset and back pressure will not be asserted until the RX FIFO level exceeds AFC_HI.

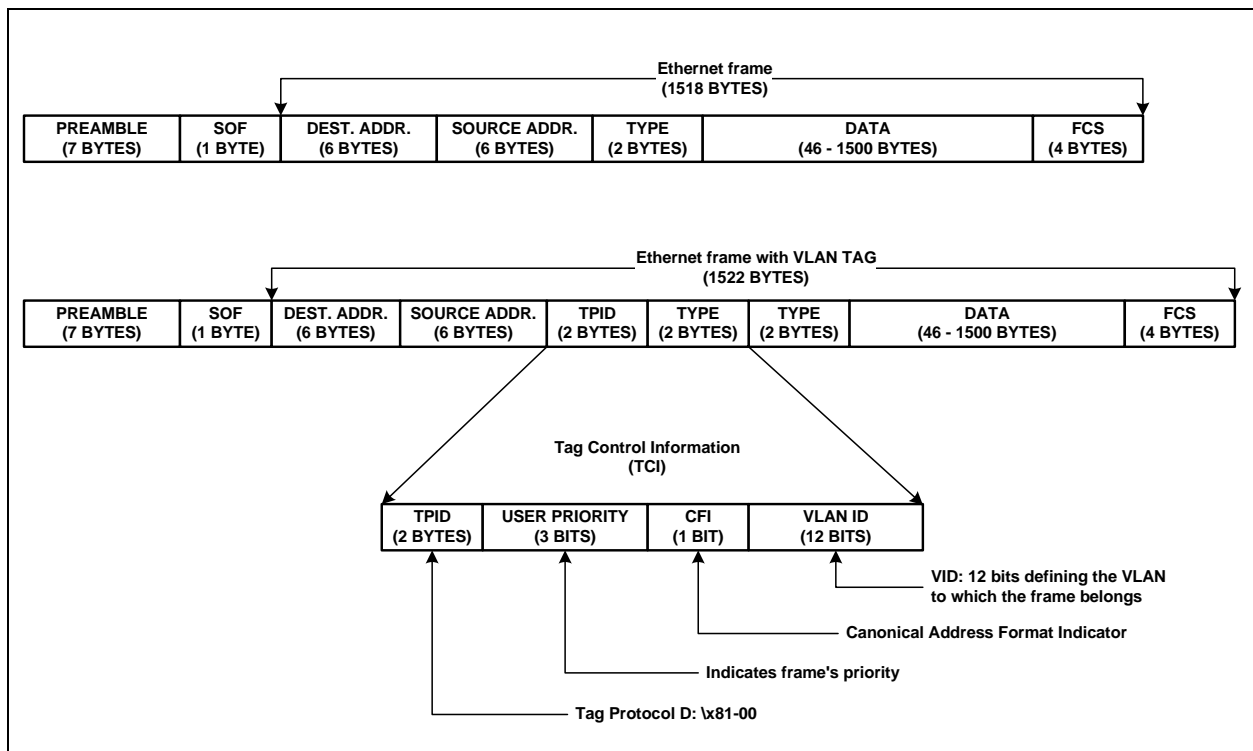

If the AFC_LO value is set to all ones (0xFF) and the AFC_HI value is set to all zeros (0x00), the flow controller will assert back pressure for received frames as if the AFC_HI threshold is always exceeded. This mechanism can be used to generate software-controlled flow control by enabling and disabling the FCANY, FCADD, FCMULT and FCBRD bits.

5.5.2 VIRTUAL LOCAL AREA NETWORK (VLAN) SUPPORT

Virtual Local Area Networks or VLANs, as defined within the IEEE 802.3 standard, provide network administrators one means of grouping nodes within a larger network into broadcast domains. To implement a VLAN, four extra bytes are added to the basic Ethernet packet. As shown in [Figure 5-9](#), the four bytes are inserted after the Source Address Field and before the Type/Length field. The first two bytes of the VLAN tag identify the tag, and by convention are set to the value 0x8100. The last two bytes identify the specific VLAN associated with the packet; they also provide a priority field.

The device supports VLAN-tagged packets. It provides two registers which are used to identify VLAN-tagged packets. One register should normally be set to the conventional VLAN ID of 0x8100. The other register provides a way of identifying VLAN frames tagged with a proprietary (not 0x8100) identifier. If a packet arrives bearing either of these tags in the two bytes succeeding the Source Address field, the controller will recognize the packet as a VLAN-tagged packet. In this case, the controller increases the maximum allowed packet size from 1518 to 1522 bytes (normally the controller filters packets larger than 1518 bytes). This allows the packet to be received, and then processed by Host software, or to be transmitted on the network.

FIGURE 5-9: VLAN FRAME

5.5.3 ADDRESS FILTERING FUNCTIONAL DESCRIPTION

The Ethernet address fields of an Ethernet Packet, consists of two 6-byte fields: one for the destination address and one for the source address. The first bit of the destination address signifies whether it is a physical address or a multicast address.

The device's address check logic filters the frame based on the Ethernet receive filter mode that has been enabled. Filter modes are specified based on the state of the control bits in [Table 5-45, "Address Filtering Modes"](#), which shows the various filtering modes used by the Ethernet MAC Function. These bits are defined in more detail in the "MAC Control Register". Please refer to [Section 7.4.1, "MAC Control Register \(MAC_CR\)," on page 159](#) for more information on this register.

If the frame fails the filter, the Ethernet MAC function does not receive the packet. The Host has the option of accepting or ignoring the packet.

TABLE 5-45: ADDRESS FILTERING MODES

| MCPAS | PRMS | INVFILT | HO | HPFILT | Description |
|-------|------|---------|----|--------|---|
| 0 | 0 | 0 | 0 | 0 | MAC address perfect filtering only for all addresses. |
| 0 | 0 | 0 | 0 | 1 | MAC address perfect filtering for physical address and hash filtering for multicast addresses |
| 0 | 0 | 0 | 1 | 1 | Hash Filtering for physical and multicast addresses |
| 0 | 0 | 1 | 0 | 0 | Inverse Filtering |
| X | 1 | 0 | X | X | Promiscuous |
| 1 | 0 | 0 | 0 | X | Pass all multicast frames. Frames with physical addresses are perfect-filtered |
| 1 | 0 | 0 | 1 | 1 | Pass all multicast frames. Frames with physical addresses are hash-filtered |

5.5.4 FILTERING MODES

5.5.4.1 Perfect Filtering

This filtering mode passes only incoming frames whose destination address field exactly matches the value programmed into the MAC Address High register and the MAC address low register. The MAC address is formed by the concatenation of the above two registers in the MAC CSR Function.

5.5.4.2 Hash Only Filtering Mode

This type of filtering checks for incoming Receive packets with either multicast or physical destination addresses, and executes an imperfect address filtering against the hash table.

During imperfect hash filtering, the destination address in the incoming frame is passed through the CRC logic and the upper six bits of the CRC register are used to index the contents of the hash table. The hash table is formed by merging the register's multicast hash table high and multicast hash table low in the MAC CSR Function to form a 64-bit hash table. The most significant bit determines the register to be used (High/Low), while the other five bits determine the bit within the register. A value of 00000 selects Bit 0 of the multicast hash table low register and a value of 11111 selects Bit 31 of the multicast hash table high register.

5.5.4.3 Hash Perfect Filtering

In hash perfect filtering, if the received frame is a physical address, the device's Packet Filter block perfect-filters the incoming frame's destination field with the value programmed into the MAC Address High register and the MAC Address Low register. If the incoming frame is a multicast frame, however, the device's packet filter function performs an imperfect address filtering against the hash table.

The imperfect filtering against the hash table is the same imperfect filtering process described in [Section 5.5.4.2, "Hash Only Filtering Mode"](#).

5.5.4.4 Inverse Filtering

In inverse filtering, the Packet Filter Block accepts incoming frames with a destination address not matching the perfect address (i.e., the value programmed into the MAC Address High register and the MAC Address Low register in the CRC block and rejects frames with destination addresses matching the perfect address.

For all filtering modes, when MCPAS is set, all multicast frames are accepted. When the PRMS bit is set, all frames are accepted regardless of their destination address. This includes all broadcast frames as well.

5.5.5 WAKEUP FRAME DETECTION

Setting the [Wakeup Frame Enable \(WUEN\)](#) bit in the [Wakeup Control and Status Register \(WUCSR\)](#), places the MAC in the wakeup frame detection mode. In this mode, normal data reception is disabled, and detection logic within the MAC examines receive data for the pre-programmed wakeup frame patterns. When a wakeup pattern is received, the [Remote Wakeup Frame Received \(WUFR\)](#) bit in the WUCSR is set, the device places itself in a fully operational state, and remote wakeup is issued. The Host will then resume the device and read the WUCSR register to determine the condition that caused the remote wakeup. Upon determining that the WUFR bit is set, the Host will know a wakeup frame detection event was the cause. The Host will then clear the WUFR bit, and clear the WUEN bit to resume normal receive operation. Please refer to [Section 7.4.12, "Wakeup Control and Status Register \(WUCSR\)," on page 172](#) for additional information on this register.

Before putting the MAC into the wakeup frame detection state, the Host must provide the detection logic with a list of sample frames and their corresponding byte masks. This information is written into the Wakeup Frame Filter register (WUFF). Please refer to [Section 7.4.11, "Wakeup Frame Filter \(WUFF\)," on page 171](#) for additional information on this register.

The number of programmable wakeup filters supported by the MAC is device dependent. [Table 5-46](#) indicates the number of wakeup frame filters contained in the WUFF of each LAN950x family device. The number of writes/reads required to program the WUFF or read its contents, respectively, is also indicated.

TABLE 5-46: WAKEUP FRAME FILTER CAPACITY

| Device | Number of Filters | Number of Writes/Reads |
|--------------------|-------------------|------------------------|
| LAN9500/LAN9500i | 4 | 20 |
| LAN9500A/LAN9500Ai | 8 | 40 |

The programmable filters support many different receive packet patterns. If remote wakeup mode is enabled, the remote wakeup function receives all frames addressed to the MAC. It then checks each frame against the enabled filter and recognizes the frame as a remote wakeup frame if it passes the WUFF's address filtering and CRC value match.

In order to determine which bytes of the frames should be checked by the CRC module, the MAC uses a programmable byte mask and a programmable pattern offset for each of the supported filters.

The pattern's offset defines the location of the first byte that should be checked in the frame. The byte mask is a 128-bit field that specifies whether or not each of the 128 contiguous bytes within the frame, beginning in the pattern offset, should be checked. If bit *j* in the byte mask is set, the detection logic checks byte offset +*j* in the frame.

In order to load the Wakeup Frame Filter register, the Host LAN driver software must perform the number of writes indicated in [Table 5-46](#) to the device's Wakeup Frame Filter register (WUFF). The contents of the Wakeup Frame Filter register may be obtained by reading it. The number of reads required to extract the entire contents of the device's WUFF is also indicated in [Table 5-46](#).

[Table 5-47](#) shows the wakeup frame filter register's structure for LAN9500/LAN9500i, while [Table 5-48](#) shows that for LAN9500A/LAN9500Ai. Component elements common to both register structures follow their definition in this section.

LAN950x

TABLE 5-47: WAKEUP FRAME FILTER REGISTER STRUCTURE (LAN9500/LAN9500I ONLY)

| | | | | | | | |

The Filter *i* Byte Mask defines which incoming frame bytes Filter *i* will examine to determine whether or not this is a Wakeup Frame. [Table 5-49](#), describes the byte mask's bit fields.

Filter *x* Mask 0 corresponds to bits [31:0]. Where the lsb corresponds to the first byte on the wire.

Filter *x* Mask 1 corresponds to bits [63:32]. Where the lsb corresponds to the first byte on the wire.

Filter *x* Mask 2 corresponds to bits [95:64]. Where the lsb corresponds to the first byte on the wire.

Filter *x* Mask 3 corresponds to bits [127:96]. Where the lsb corresponds to the first byte on the wire.

The following tables define elements common to both WUFF register structures.

TABLE 5-49: FILTER I BYTE MASK BIT DEFINITIONS

| FILTER I BYTE MASK DESCRIPTION | |
|--------------------------------|--|
| Bits | Description |
| 127:0 | Byte Mask: If bit <i>j</i> of the byte mask is set, the CRC machine processes byte <i>pattern-offset + j</i> of the incoming frame. Otherwise, byte <i>pattern-offset + j</i> is ignored. |

The Filter *i* command register controls Filter *i* operation. [Table 5-50](#) shows the Filter *I* command register.

TABLE 5-50: FILTER I COMMAND BIT DEFINITIONS

| FILTER I COMMANDS | |
|-------------------|--|
| Bits | Description |
| 3:2 | Address Type: Defines the destination address type of the pattern. 00 = Pattern applies only to unicast frames. 10 = Pattern applies only to multicast frames. X1 = Pattern applies to all frames that have passed the regular receive filter. |
| 1 | RESERVED |
| 0 | Enable Filter: When bit is set, Filter i is enabled, otherwise, Filter i is disabled. |

The Filter i Offset register defines the offset in the frame's destination address field from which the frames are examined by Filter i. [Table 5-51](#) describes the Filter i Offset bit fields.

TABLE 5-51: FILTER I OFFSET BIT DEFINITIONS

| FILTER I OFFSET DESCRIPTION | |
|-----------------------------|---|
| Bits | Description |
| 7:0 | Pattern Offset: The offset of the first byte in the frame on which CRC is checked for Wakeup Frame recognition. The MAC checks the first offset byte of the frame for CRC and checks to determine whether the frame is a Wakeup Frame. Offset 0 is the first byte of the incoming frame's destination address. |

The Filter i CRC-16 register contains the CRC-16 result of the frame that should pass Filter i.

[Table 5-52](#) describes the Filter i CRC-16 bit fields.

TABLE 5-52: FILTER I CRC-16 BIT DEFINITIONS

| FILTER I CRC-16 DESCRIPTION | |
|-----------------------------|---|
| Bits | Description |
| 15:0 | Pattern CRC-16: This field contains the 16-bit CRC value from the pattern and the byte mask programmed to the Wakeup Filter register function. This value is compared against the CRC calculated on the incoming frame, and a match indicates the reception of a Wakeup Frame. |

[Table 5-53](#) indicates the cases that produce a wake when the [Wakeup Frame Enable \(WUEN\)](#) bit of the [Wakeup Control and Status Register \(WUCSR\)](#) is set. All other cases do not generate a wake.

TABLE 5-53: WAKEUP GENERATION CASES

| Filter Enabled (Note 5-21) | CRC Match (Note 5-22) | Global Unicast Enabled (Note 5-23) | Pass Regular Receive Filter | Address Type (Note 5-24) | Broad-cast Frame (Note 5-25) | Multi-cast Frame | Unicast Frame |
|---|--|---|-----------------------------|---|---|------------------|---------------|
| Yes | Yes | x | x | x | Yes | No | No |
| Yes | Yes | Yes | x | x | No | No | Yes |
| Yes | Yes | x | Yes | Multicast (=10) | No | Yes | No |
| Yes | Yes | x | Yes | Unicast (=00) | No | No | Yes |
| Yes | Yes | x | Yes | Passed Receive Filter (=x1b) | x | x | x |

Note 5-21 As determined by bit 0 of Filter i Command.

Note 5-22 CRC matches Filter i CRC-16 field.

Note 5-23 As determined by bit 9 of WUCSR.

Note 5-24 As determined by bits 3:2 of Filter i Command.

Note 5-25 When wakeup frame detection is enabled via the [Wakeup Frame Enable \(WUEN\)](#) bit of the [Wakeup Control and Status Register \(WUCSR\)](#), a broadcast wakeup frame will wake up the device despite the state of the [Disable Broadcast Frames \(BCAST\)](#) bit in the [MAC Control Register \(MAC_CR\)](#).

Note: x indicates "don't care".

5.5.6 MAGIC PACKET DETECTION

Setting the [Magic Packet Enable \(MPEN\)](#) bit in the [Wakeup Control and Status Register \(WUCSR\)](#), places the MAC in the "Magic Packet" detection mode. In this mode, normal data reception is disabled, and detection logic within the MAC examines receive data for a Magic Packet. When a Magic Packet is received, the [Magic Packet Received \(MPR\)](#) bit in the WUCSR is set, the device places itself in a fully operational state, and remote wakeup is issued. The Host will then resume the device and read the WUCSR register to determine the condition that caused the remote wakeup. Upon determining that the MPR bit is set, the Host will know reception of a Magic Packet was the cause. The Host will then clear the MPR bit, and clear the MPEN bit to resume normal receive operation. Please refer to [Section 7.4.12, "Wakeup Control and Status Register \(WUCSR\)," on page 172](#) for additional information on this register.

In Magic Packet mode, the Power Management Logic constantly monitors each frame addressed to the node for a specific Magic Packet pattern. It checks only packets with the MAC's address or a broadcast address to meet the Magic Packet requirement. The Power Management Logic checks each received frame for the pattern 48h FF_FF_FF_FF_FF_FF after the destination and source address field.

Then the Function looks in the frame for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 address repetitions, the PMT Function scans for the 48'hFF_FF_FF_FF_FF_FF pattern again in the incoming frame.

The 16 repetitions may be anywhere in the frame but must be preceded by the synchronization stream. The device will also accept a multicast frame, as long as it detects the 16 duplications of the MAC address. If the MAC address of a node is 00h 11h 22h 33h 44h 55h, then the MAC scans for the following data sequence in an Ethernet: Frame.

```
Destination Address Source Address .....FF FF FF FF FF FF
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
...CRC
```

5.5.7 RECEIVE CHECKSUM OFFLOAD ENGINE (RXCOE)

The receive checksum offload engine provides assistance to the Host by calculating a 16-bit checksum for a received Ethernet frame. The RXCOE readily supports the following IEEE802.3 frame formats:

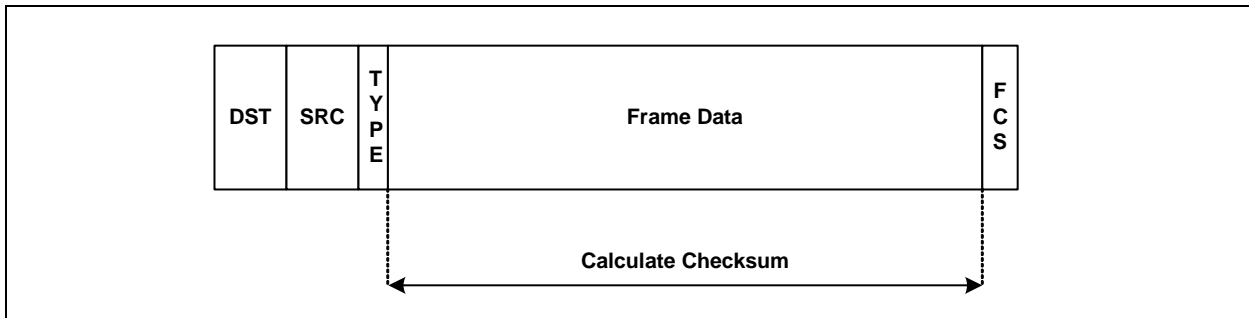

- Type II Ethernet frames
- SNAP encapsulated frames
- Support for up to 2, 802.1q VLAN tags

The resulting checksum value can also be modified by software to support other frame formats.

The RXCOE has two modes of operation. In mode 0, the RXCOE calculates the checksum between the first 14 bytes of the Ethernet frame and the FCS. This is illustrated in [Figure 5-10](#).

LAN950x

FIGURE 5-10: RXCOE CHECKSUM CALCULATION

In mode 1, the RXCOE supports VLAN tags and a SNAP header. In this mode, the RXCOE calculates the checksum at the start of L3 packet. The VLAN1 tag register is used by the RXCOE to indicate what protocol type is to be used to indicate the existence of a VLAN tag. This value is typically 8100h.

Example frame configurations:

FIGURE 5-11: TYPE II ETHERNET FRAME

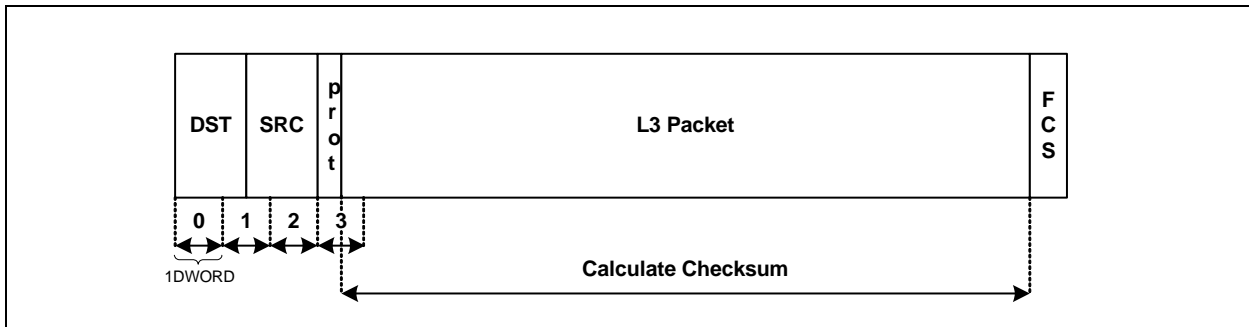

FIGURE 5-12: ETHERNET FRAME WITH VLAN TAG

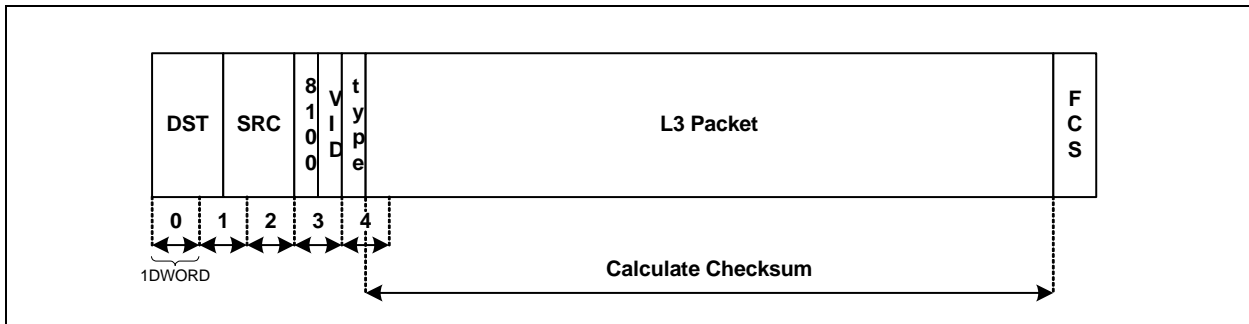

FIGURE 5-13: ETHERNET FRAME WITH LENGTH FIELD AND SNAP HEADER

FIGURE 5-14: ETHERNET FRAME WITH VLAN TAG AND SNAP HEADER

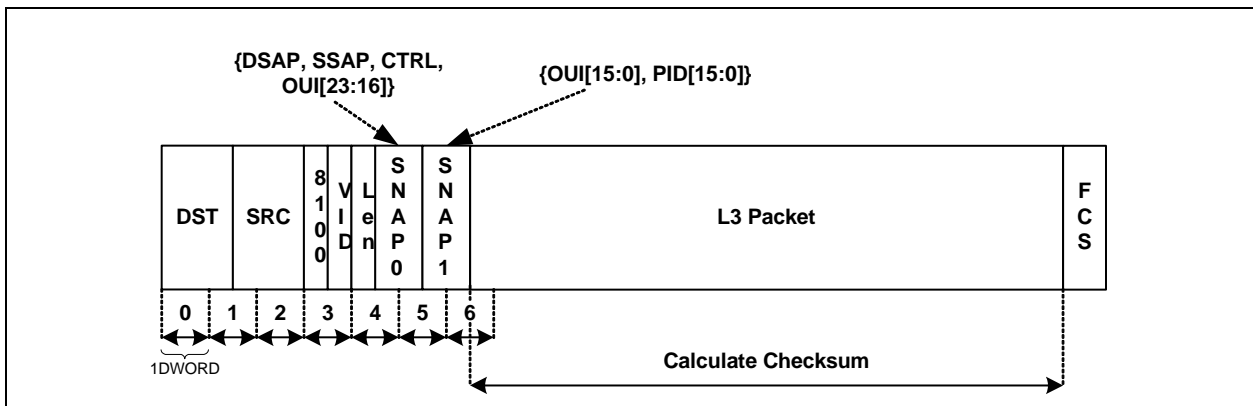

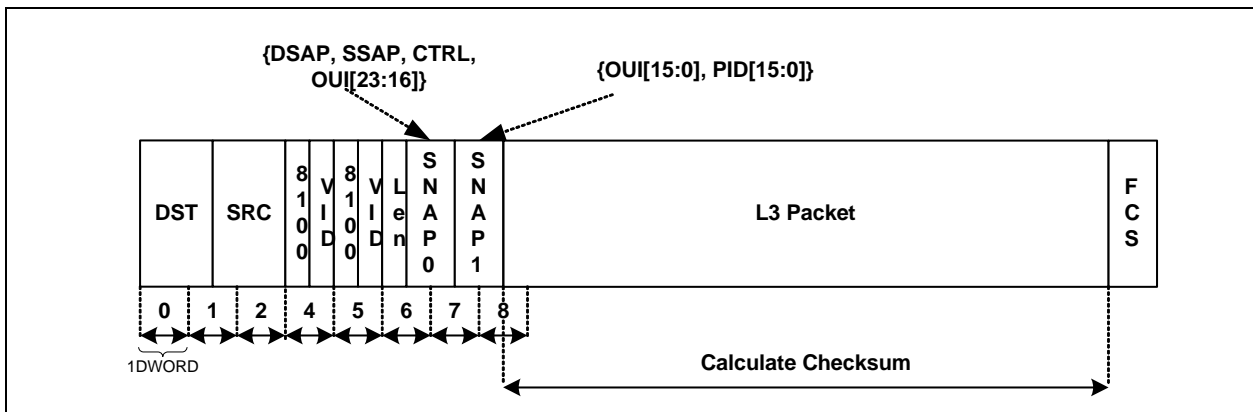

FIGURE 5-15: ETHERNET FRAME WITH MULTIPLE VLAN TAGS AND SNAP HEADER

The RXCOE supports a maximum of two VLAN tags. If there are more than two VLAN tags, the VLAN protocol identifier for the third tag is treated as an Ethernet type field. The checksum calculation will begin immediately after the type field.

LAN950x

The RXCOE resides in the RX path within the MAC. As the RXCOE receives an Ethernet frame, it calculates the 16-bit checksum. The RXCOE passes the Ethernet frame to the RX FIFO with the checksum appended to the end of the frame. The RXCOE inserts the checksum immediately after the last byte of the Ethernet frame and before it transmits the status word. The packet length field in the RX Status Word (refer to [Section 5.4.1.2](#)) will indicate that the frame size has increased by two bytes to accommodate the checksum.

Note: When enabled, the RXCOE calculates a checksum for every received frame.

Setting the RXCOE_EN bit in the [Checksum Offload Engine Control Register \(COE_CR\)](#) enables the RXCOE, while the RXCOE_MODE bit selects the operating mode. When the RXCOE is disabled, the received data is simply passed through the RXCOE unmodified.

Note 1: Software applications must stop the receiver and flush the RX data path before changing the state of the RXCOE_EN or RXCOE_MODE bits.

2: When the RXCOE is enabled, automatic pad stripping must be disabled (bit 8 (PADSTR) of the [MAC Control Register \(MAC_CR\)](#)) and vice versa. These functions cannot be enabled simultaneously.

5.5.7.1 RX Checksum Calculation

The checksum is calculated 16 bits at a time. In the case of an odd sized frame, an extra byte of zero is used to pad up to 16 bits.

Consider the following packet: DA, SA, Type, B0, B1, B2 ... BN, FCS

Let $[A, B] = A * 256 + B$;

If the packet has an even number of octets then

checksum = $[B1, B0] + C0 + [B3, B2] + C1 + \dots + [BN, BN-1] + CN-1$

Where C0, C1, ... CN-1 are the carry out results of the intermediate sums.

If the packet has an odd number of octets then

checksum = $[B1, B0] + C0 + [B3, B2] + C1 + \dots + [0, BN] + CN-1$

5.5.8 TRANSMIT CHECKSUM OFFLOAD ENGINE (TXCOE)

The transmit checksum offload engine provides assistance to the CPU by calculating a 16-bit checksum, typically for TCP, for a transmit Ethernet frame. The TXCOE calculates the checksum and inserts the results back into the data stream as it is transferred to the MAC.

To activate the TXCOE and perform a checksum calculation, the Host must first set the [TX Checksum Offload Engine Enable \(TX_COE_EN\)](#) bit in the [Checksum Offload Engine Control Register \(COE_CR\)](#). The Host then pre-pends a 3 DWORD buffer to the data that will be transmitted. The pre-pended buffer includes a TX Command A, TX Command B, and a 32-bit TX checksum preamble (refer to [Table 5-54](#)). When the CK bit of the TX Command 'B' is set in conjunction with the FS bit of TX Command 'A' and the TX_COE_EN bit of the COE_CR register, the TXCOE will perform a checksum calculation on the associated packet. The TX checksum preamble instructs the TXCOE on the handling of the associated packet. The [TXCSSP - TX Checksum Start Pointer](#) field of the TX checksum preamble defines the byte offset at which the data checksum calculation will begin. The checksum calculation will begin at this offset and will continue until the end of the packet. The data checksum calculation must not begin in the MAC header (first 14 bytes) or in the last 4 bytes of the TX packet. When the calculation is complete, the checksum will be inserted into the packet at the byte offset defined by the [TXCSLOC - TX Checksum Location](#) field of the TX checksum preamble. The TX checksum cannot be inserted in the MAC header (first 14 bytes) or in the last 4 bytes of the TX packet. If the CK bit is not set in the first TX Command 'B' of a packet, the packet is passed directly through the TXCOE without modification, regardless if the TXCOE_EN is set. An example of a TX packet with a pre-pended TX checksum preamble can be found in [Section 5.4.2.9, "TX Example 3"](#). In this example, the Host provides the Ethernet frame to the Ethernet controller (via a USB packet) in four fragments, the first containing the TX Checksum Preamble. [Figure 5-8](#) shows how these fragments are loaded into the TX Data FIFO. For more information on the TX Command 'A' and TX Command 'B', refer to [Section 5.4.2.1, "TX Command Format," on page 47](#).

If the TX packet already includes a partial checksum calculation (perhaps inserted by an upper layer protocol), this checksum can be included in the hardware checksum calculation by setting the TXCSSP field in the TX checksum preamble to include the partial checksum. The partial checksum can be replaced by the completed checksum calculation by setting the TXCSLOC pointer to point to the location of the partial checksum.

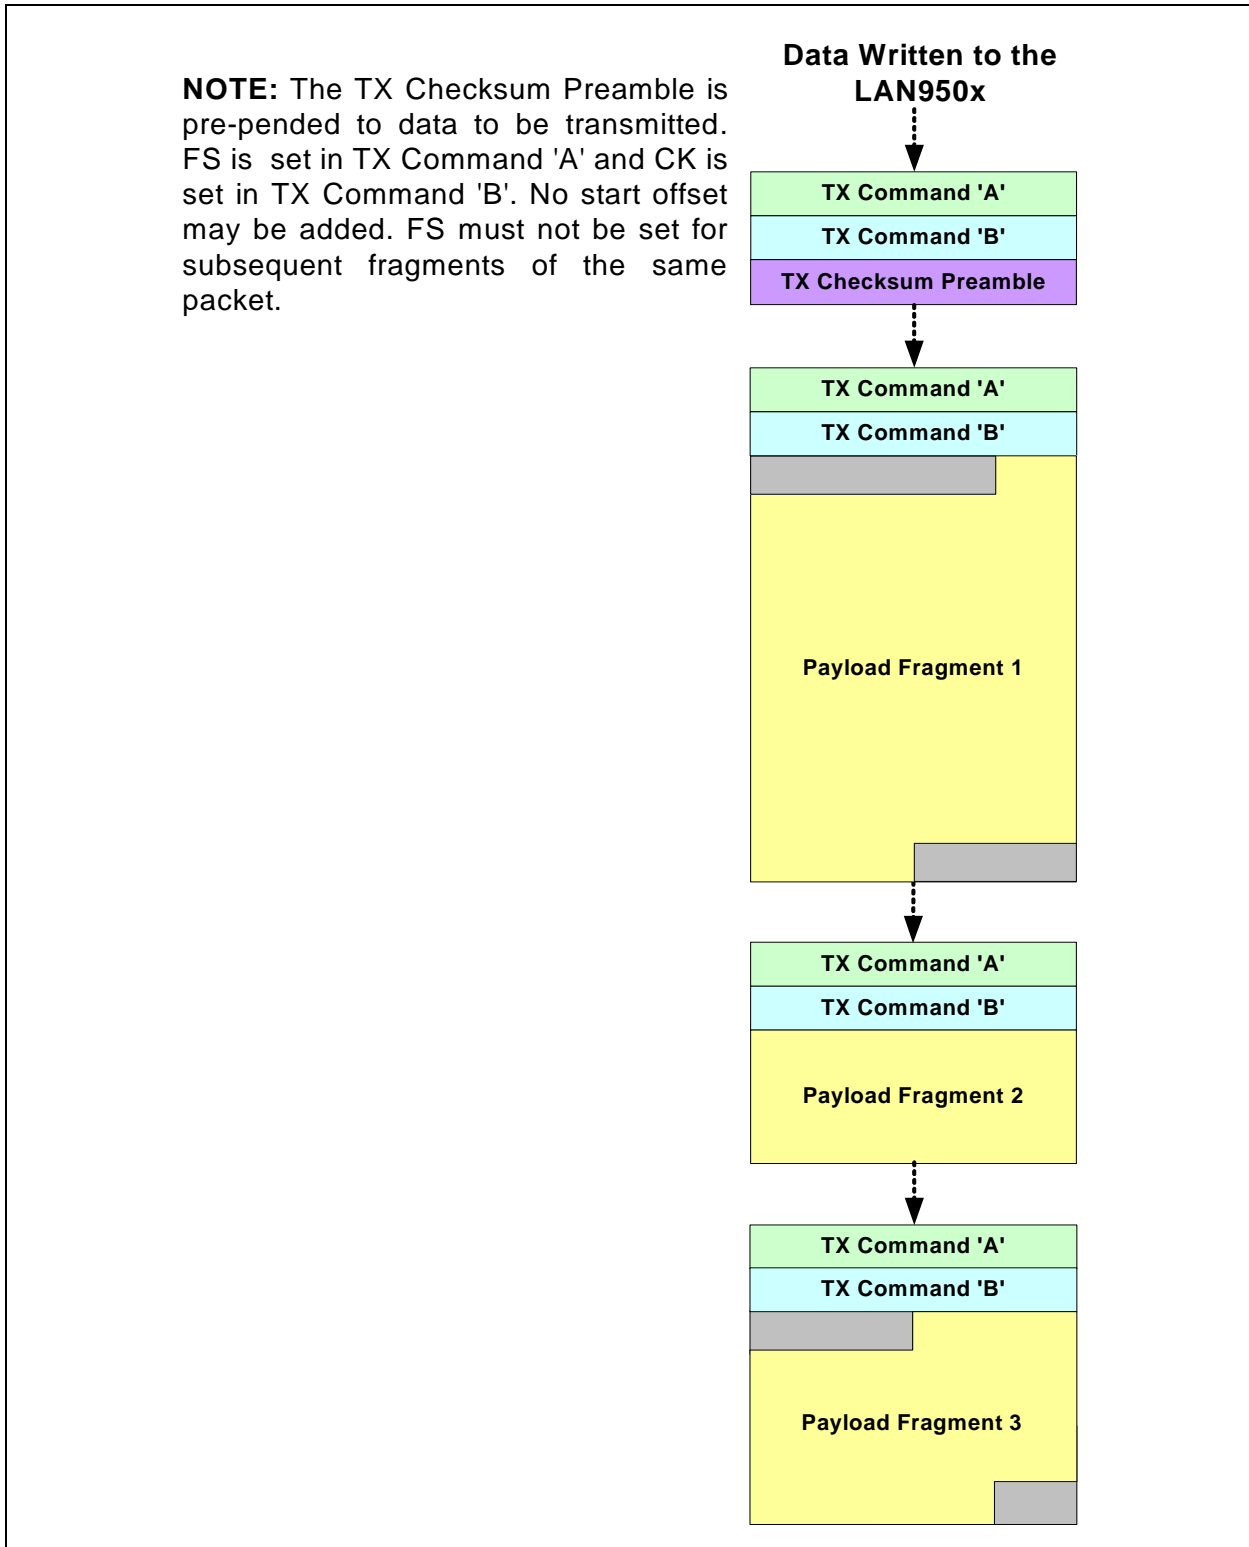

TABLE 5-54: TX CHECKSUM PREAMBLE

| FIELD | DESCRIPTION |
|-------|---|
| 31:28 | RESERVED |
| 27:16 | <p>TXCSLOC - TX Checksum Location This field specifies the byte offset where the TX checksum will be inserted in the TX packet. The checksum will replace two bytes of data starting at this offset.</p> <p>Note: The TX checksum cannot be inserted in the MAC header (first 14 bytes) or in the last 4 bytes of the TX packet.</p> |
| 15:12 | RESERVED |
| 11:0 | <p>TXCSSP - TX Checksum Start Pointer This field indicates start offset, in bytes, where the checksum calculation will begin in the associated TX packet.</p> <p>Note: The data checksum calculation must not begin in the MAC header (first 14 bytes) or in the last 4 bytes of the TX packet.</p> |

- Note 1:** When the TXCOE is enabled, the third DWORD of the pre-pended packet is not transmitted. However, 4 bytes must be added to the packet length field in TX Command B.
- 2:** Software applications must stop the transmitter and flush the TX data path before changing the state of the TXCOE_EN bit. However, the CK bit of TX Command B can be set or cleared on a per-packet basis.
 - 3:** The TXCOE_MODE may only be changed if the TX path is disabled. If it is desired to change this value during run time, it is safe to do so only after the TX Ethernet path is disabled and the TLI is empty.
 - 4:** The TX checksum preamble must be DWORD-aligned.
 - 5:** TX preamble size is accounted for in both the buffer length and packet length.
 - 6:** The first buffer, which contains the TX preamble, may not contain any Ethernet frame data

FIGURE 5-16: [TX Example Illustrating a Pre-pended TX Checksum Preamble on page 68](#) illustrates the use of a pre-pended checksum preamble when transmitting an Ethernet frame consisting of 3 payload buffers.

FIGURE 5-16: TX EXAMPLE ILLUSTRATING A PRE-PENDED TX CHECKSUM PREAMBLE

5.5.8.1 TX Checksum Calculation

The TX checksum calculation is performed using the same operation as the RX checksum shown in [Section 5.5.7.1](#), with the exception that the calculation starts as indicated by the preamble, and the transmitted checksum is the one's-complement of the final calculation.

Note: When the TX checksum offload feature is invoked, if the calculated checksum is 0000h, it is left unaltered. UDP checksums are optional under IPv4, and a zero checksum calculated by the TX checksum offload feature will erroneously indicate to the receiver that no checksum was calculated, however, the packet will typically not be rejected by the receiver. Under IPv6, however, according to RFC 2460, the UDP checksum is not optional. A calculated checksum that yields a result of zero must be changed to FFFFh for insertion into the UDP header. IPv6 receivers discard UDP packets containing a zero checksum. **Thus, this feature must not be used for UDP checksum calculation under IPv6.**

5.5.9 MAC CONTROL AND STATUS REGISTERS (MCSR)

Please refer to [Section 7.4, "MAC Control and Status Registers,"](#) on page 158 for a complete description of the MCSR.

5.6 10/100 Internal Ethernet PHY

The device integrates an IEEE 802.3 Physical Layer for Twisted Pair Ethernet applications. The PHY can be configured for either 100 Mbps (100Base-TX) or 10 Mbps (10Base-T) Ethernet operation in either Full or Half Duplex configurations. The PHY block includes auto-negotiation. Minimal external components are required for the utilization of the internal PHY.

The device provides an option to use an external PHY in place of the internal PHY. The external PHY can be connected via the Media Independent Interface (MII) port. This option is useful for supporting Home PNA operations. When an external PHY is used, the internal PHY must be placed into general power down via a PHY reset (refer to [Section 5.6.9, "PHY Resets,"](#) on page 78 for further information).

Functionally, the internal PHY can be divided into the following sections:

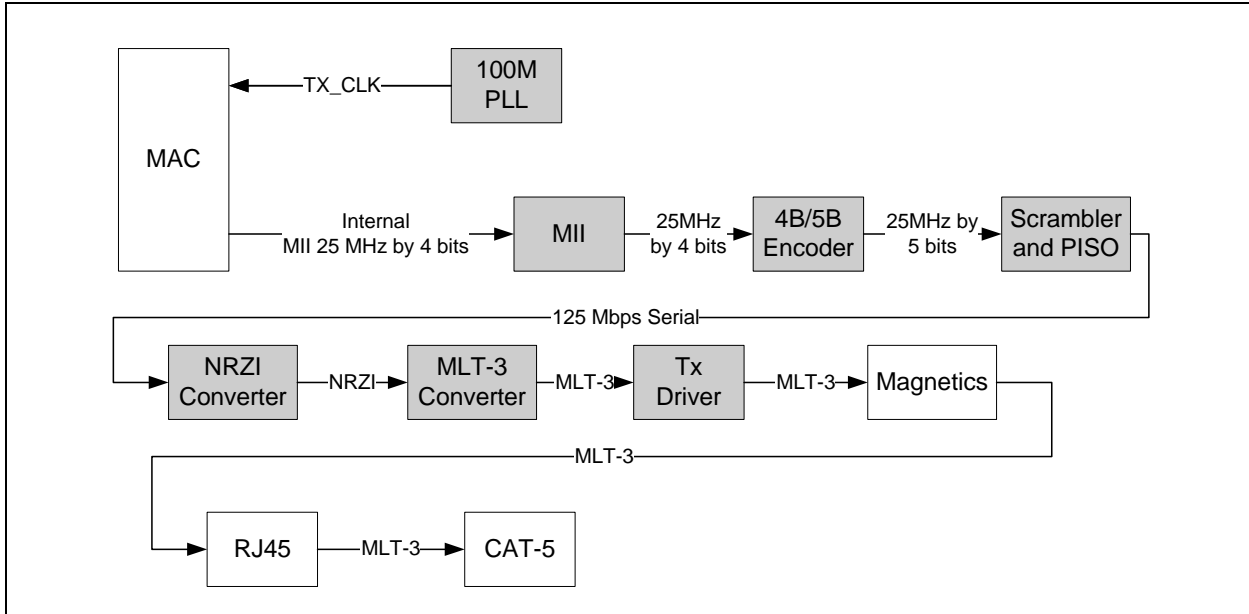

- 100Base-TX transmit and receive
- 10Base-T transmit and receive
- Internal MII interface to the Ethernet Media Access Controller
- Auto-negotiation to automatically determine the best speed and duplex possible
- Management Control to read status registers and write control registers

5.6.1 100BASE-TX TRANSMIT

The data path of the 100Base-TX is shown in [Figure 5-17](#). Each major block is explained in the following sections.

LAN950x

FIGURE 5-17: 100BASE-TX DATA PATH

5.6.1.1 4B/5B Encoding

The transmit data passes from the MII block to the 4B/5B encoder. This block encodes the data from 4-bit nibbles to 5-bit symbols (known as “code-groups”) according to [Table 5-55](#). Each 4-bit data-nibble is mapped to 16 of the 32 possible code-groups. The remaining 16 code-groups are either used for control information or are not valid.

The first 16 code-groups are referred to by the hexadecimal values of their corresponding data nibbles, 0 through F. The remaining code-groups are given letter designations with slashes on either side. For example, an IDLE code-group is /I/, a transmit error code-group is /H/, etc.

The encoding process may be bypassed by clearing bit 6 of register 31. When the encoding is bypassed the 5th transmit data bit is equivalent to TX_ER.

TABLE 5-55: 4B/5B CODE TABLE

| Code Group | SYM | Receiver Interpretation | | | Transmitter Interpretation | | |
|------------|-----|-------------------------|------|------|----------------------------|------|------|
| 11110 | 0 | 0 | 0000 | DATA | 0 | 0000 | DATA |
| 01001 | 1 | 1 | 0001 | | 1 | 0001 | |

TABLE 5-55: 4B/5B CODE TABLE (CONTINUED)

| Code Group | SYM | Receiver Interpretation | | | Transmitter Interpretation | | |
|------------|-----|---|------|--|-----------------------------|------|--|
| | | F | 1111 | | F | 1111 | |
| 11101 | F | F | 1111 | | F | 1111 | |
| 11111 | I | IDLE | | | Sent after /T/R until TX_EN | | |
| 11000 | J | First nibble of SSD, translated to "0101" following IDLE, else RX_ER | | | Sent for rising TX_EN | | |
| 10001 | K | Second nibble of SSD, translated to "0101" following J, else RX_ER | | | Sent for rising TX_EN | | |
| 01101 | T | First nibble of ESD, causes de-assertion of CRS if followed by /R/, else assertion of RX_ER | | | Sent for falling TX_EN | | |
| 00111 | R | Second nibble of ESD, causes deassertion of CRS if following /T/, else assertion of RX_ER | | | Sent for falling TX_EN | | |
| 00100 | H | Transmit Error Symbol | | | Sent for rising TX_ER | | |
| 00110 | V | INVALID, RX_ER if during RX_DV | | | INVALID | | |
| 11001 | V | INVALID, RX_ER if during RX_DV | | | INVALID | | |
| 00000 | V | INVALID, RX_ER if during RX_DV | | | INVALID | | |
| 00001 | V | INVALID, RX_ER if during RX_DV | | | INVALID | | |
| 00010 | V | INVALID, RX_ER if during RX_DV | | | INVALID | | |
| 00011 | V | INVALID, RX_ER if during RX_DV | | | INVALID | | |
| 00101 | V | INVALID, RX_ER if during RX_DV | | | INVALID | | |
| 01000 | V | INVALID, RX_ER if during RX_DV | | | INVALID | | |
| 01100 | V | INVALID, RX_ER if during RX_DV | | | INVALID | | |
| 10000 | V | INVALID, RX_ER if during RX_DV | | | INVALID | | |

5.6.1.2 Scrambling

Repeated data patterns (especially the IDLE code-group) can have power spectral densities with large narrow-band peaks. Scrambling the data helps eliminate these peaks and spread the signal power more uniformly over the entire channel bandwidth. This uniform spectral density is required by FCC regulations to prevent excessive EMI from being radiated by the physical wiring.

The scrambler also performs the Parallel In Serial Out conversion (PISO) of the data.

5.6.1.3 NRZI and MLT3 Encoding

The scrambler block passes the 5-bit wide parallel data to the NRZI converter where it becomes a serial 125MHz NRZI data stream. The NRZI is encoded to MLT-3. MLT3 is a tri-level code where a change in the logic level represents a code bit "1" and the logic output remaining at the same level represents a code bit "0".

5.6.1.4 100M Transmit Driver

The MLT3 data is then passed to the analog transmitter, which launches the differential MLT-3 signal, on outputs TXP and TXN, to the twisted pair media via a 1:1 ratio isolation transformer. The 10Base-T and 100Base-TX signals pass through the same transformer so that common "magnetics" can be used for both. The transmitter drives into the 100Ω impedance of the CAT-5 cable. Cable termination and impedance matching require external components.

5.6.1.5 100M Phase Lock Loop (PLL)

The 100M PLL locks onto reference clock and generates the 125MHz clock used to drive the 125 MHz logic and the 100Base-Tx Transmitter.

5.6.2 100BASE-TX RECEIVE

The receive data path is shown in [Figure 5-18](#). Detailed descriptions are given in the following subsections.

FIGURE 5-18: RECEIVE DATA PATH

5.6.2.1 100M Receive Input

The MLT-3 from the cable is fed into the PHY (on inputs RXP and RXN) via a 1:1 ratio transformer. The ADC samples the incoming differential signal at a rate of 125M samples per second. Using a 64-level quantizer, it generates 6 digital bits to represent each sample. The DSP adjusts the gain of the ADC according to the observed signal levels such that the full dynamic range of the ADC can be used.

5.6.2.2 Equalizer, Baseline Wander Correction and Clock and Data Recovery

The 6 bits from the ADC are fed into the DSP block. The equalizer in the DSP section compensates for phase and amplitude distortion caused by the physical channel consisting of magnetics, connectors, and CAT-5 cable. The equalizer can restore the signal for any good-quality CAT-5 cable between 1m and 150m.

If the DC content of the signal is such that the low-frequency components fall below the low frequency pole of the isolation transformer, then the droop characteristics of the transformer will become significant and Baseline Wander (BLW) on the received signal will result. To prevent corruption of the received data, the PHY corrects for BLW and can receive the ANSI X3.263-1995 FDDI TP-PMD defined "killer packet" with no bit errors.

The 100M PLL generates multiple phases of the 125MHz clock. A multiplexer, controlled by the timing unit of the DSP, selects the optimum phase for sampling the data. This is used as the received recovered clock. This clock is used to extract the serial data from the received signal.

5.6.2.3 NRZI and MLT-3 Decoding

The DSP generates the MLT-3 recovered levels that are fed to the MLT-3 converter. The MLT-3 is then converted to an NRZI data stream.

5.6.2.4 Descrambling

The descrambler performs an inverse function to the scrambler in the transmitter and also performs the Serial In Parallel Out (SIPO) conversion of the data.

During reception of IDLE (/I) symbols, the descrambler synchronizes its descrambler key to the incoming stream. Once synchronization is achieved, the descrambler locks on this key and is able to descramble incoming data.

Special logic in the descrambler ensures synchronization with the remote PHY by searching for IDLE symbols within a window of 4000 bytes (40us). This window ensures that a maximum packet size of 1514 bytes, allowed by the IEEE 802.3 standard, can be received with no interference. If no IDLE-symbols are detected within this time-period, receive operation is aborted and the descrambler re-starts the synchronization process.

The descrambler can be bypassed by setting bit 0 of register 31.

5.6.2.5 Alignment

The de-scrambled signal is then aligned into 5-bit code-groups by recognizing the /J/K/ Start-of-Stream Delimiter (SSD) pair at the start of a packet. Once the code-word alignment is determined, it is stored and utilized until the next start of frame.

5.6.2.6 5B/4B Decoding

The 5-bit code-groups are translated into 4-bit data nibbles according to the 4B/5B table. The SSD, /J/K/, is translated to "0101 0101" as the first 2 nibbles of the MAC preamble. Reception of the SSD causes the PHY to assert the internal RX_DV signal, indicating that valid data is available on the Internal RXD bus. Successive valid code-groups are translated to data nibbles. Reception of either the End of Stream Delimiter (ESD) consisting of the /T/R/ symbols, or at least two // symbols causes the PHY to de-assert the internal carrier sense and RX_DV.

These symbols are not translated into data.

5.6.2.7 Receiver Errors

During a frame, unexpected code-groups are considered receive errors. Expected code groups are the DATA set (0 through F), and the /T/R/ (ESD) symbol pair. When a receive error occurs, the internal MII's RX_ER signal is asserted and arbitrary data is driven onto the internal receive data bus (RXD) to the MAC. Should an error be detected during the time that the /J/K/ delimiter is being decoded (bad SSD error), RX_ER is asserted and the value 1110b is driven onto the internal receive data bus (RXD) to the MAC. Note that the internal MII's data valid signal (RX_DV) is not yet asserted when the bad SSD occurs.

5.6.3 10BASE-T TRANSMIT

Data to be transmitted comes from the MAC layer controller. The 10Base-T transmitter receives 4-bit nibbles from the MII at a rate of 2.5MHz and converts them to a 10Mbps serial data stream. The data stream is then Manchester encoded and sent to the analog transmitter, which drives a signal onto the twisted pair via the external magnetics.

The 10M transmitter uses the following blocks:

- MII (digital)
- TX 10M (digital)
- 10M Transmitter (analog)
- 10M PLL (analog)

5.6.3.1 10M Transmit Data Across the Internal MII Bus

The MAC controller drives the transmit data onto the internal TXD BUS. When the controller has driven TX_EN high to indicate valid data, the data is latched by the MII block on the rising edge of TX_CLK. The data is in the form of 4-bit wide 2.5MHz data.

5.6.3.2 Manchester Encoding

The 4-bit wide data is sent to the TX10M block. The nibbles are converted to a 10Mbps serial NRZI data stream. The 10M PLL locks onto the external clock or internal oscillator and produces a 20MHz clock. This is used to Manchester encode the NRZ data stream. When no data is being transmitted (TX_EN is low), the TX10M block outputs Normal Link Pulses (NLPs) to maintain communications with the remote link partner.

5.6.3.3 10M Transmit Drivers

The Manchester encoded data is sent to the analog transmitter where it is shaped and filtered before being driven out as a differential signal across the TXP and TXN outputs.

LAN950x

5.6.4 10BASE-T RECEIVE

The 10Base-T receiver gets the Manchester encoded analog signal from the cable via the magnetics. It recovers the receive clock from the signal and uses this clock to recover the NRZI data stream. This 10M serial data is converted to 4-bit data nibbles which are passed to the controller across the MII at a rate of 2.5MHz.

This 10M receiver uses the following blocks:

- Filter and SQUELCH (analog)
- 10M PLL (analog)
- RX 10M (digital)
- MII (digital)

5.6.4.1 10M Receive Input and Squelch

The Manchester signal from the cable is fed into the PHY (on inputs RXP and RXN) via 1:1 ratio magnetics. It is first filtered to reduce any out-of-band noise. It then passes through a SQUELCH circuit. The SQUELCH is a set of amplitude and timing comparators that normally reject differential voltage levels below 300mV and detect and recognize differential voltages above 585mV.

5.6.4.2 Manchester Decoding

The output of the SQUELCH goes to the RX10M block where it is validated as Manchester encoded data. The polarity of the signal is also checked. If the polarity is reversed (local RXP is connected to RXN of the remote partner and vice versa), then this is identified and corrected. The reversed condition is indicated by the flag "XPOL", bit 4 in register 27. The 10M PLL is locked onto the received Manchester signal and from this, generates the received 20MHz clock. Using this clock, the Manchester encoded data is extracted and converted to a 10MHz NRZI data stream. It is then converted from serial to 4-bit wide parallel data.

The RX10M block also detects valid 10Base-T IDLE signals - Normal Link Pulses (NLPs) - to maintain the link.

5.6.4.3 Jabber Detection

Jabber is a condition in which a station transmits for a period of time longer than the maximum permissible packet length, usually due to a fault condition, that results in holding the TX_EN input for a long period. Special logic is used to detect the jabber state and abort the transmission to the line, within 45 mS. Once TX_EN is deasserted, the logic resets the jabber condition.

5.6.5 AUTO-NEGOTIATION

The purpose of the Auto-negotiation function is to automatically configure the PHY to the optimum link parameters based on the capabilities of its link partner. Auto-negotiation is a mechanism for exchanging configuration information between two link-partners and automatically selecting the highest performance mode of operation supported by both sides. Auto-negotiation is fully defined in clause 28 of the IEEE 802.3 specification.

Once auto-negotiation has completed, information about the resolved link can be passed back to the controller via the internal Serial Management Interface (SMI). The results of the negotiation process are reflected in the Speed Indication bits in register 31, as well as the Link Partner Ability Register (Register 5).

The auto-negotiation protocol is a purely physical layer activity and proceeds independently of the MAC controller.

The advertised capabilities of the PHY are stored in register 4 of the SMI registers. The default advertised by the PHY is determined by user-defined on-chip signal options.

The following blocks are activated during an Auto-negotiation session:

- Auto-negotiation (digital)
- 100M ADC (analog)
- 100M PLL (analog)
- 100M equalizer/BLW/clock recovery (DSP)
- 10M SQUELCH (analog)
- 10M PLL (analog)
- 10M Transmitter (analog)

When enabled, auto-negotiation is started by the occurrence of one of the following events:

- Hardware reset
- Software reset
- Power-down reset
- Link status down
- Setting register 0, bit 9 high (auto-negotiation restart)

On detection of one of these events, the PHY begins auto-negotiation by transmitting bursts of Fast Link Pulses (FLP). These are bursts of link pulses from the 10M transmitter. They are shaped as Normal Link Pulses and can pass uncorrupted down CAT-3 or CAT-5 cable. A Fast Link Pulse Burst consists of up to 33 pulses. The 17 odd-numbered pulses, which are always present, frame the FLP burst. The 16 even-numbered pulses, which may be present or absent, contain the data word being transmitted. Presence of a data pulse represents a “1”, while absence represents a “0”.

The data transmitted by an FLP burst is known as a “Link Code Word.” These are defined fully in IEEE 802.3 clause 28. In summary, the PHY advertises 802.3 compliance in its selector field (the first 5 bits of the Link Code Word). It advertises its technology ability according to the bits set in register 4 of the SMI registers.

There are 4 possible matches of the technology abilities. In the order of priority these are:

- 100M full-duplex (Highest priority)
- 100M half-duplex
- 10M full-duplex
- 10M half-duplex

If the full capabilities of the PHY are advertised (100M, full-duplex), and if the link partner is capable of 10M and 100M, then auto-negotiation selects 100M as the highest performance mode. If the link partner is capable of half and full-duplex modes, then auto-negotiation selects full-duplex as the highest performance operation.

Once a capability match has been determined, the link code words are repeated with the acknowledge bit set. Any difference in the main content of the link code words at this time will cause auto-negotiation to re-start. Auto-negotiation will also re-start if not all of the required FLP bursts are received.

Writing register 4 bits [8:5] allows software control of the capabilities advertised by the PHY. Writing register 4 does not automatically re-start auto-negotiation. Register 0, bit 9 must be set before the new abilities will be advertised. Auto-negotiation can also be disabled via software by clearing register 0, bit 12.

The device does not support “Next Page” capability.

5.6.6 PARALLEL DETECTION

If LAN950x is connected to a device lacking the ability to auto-negotiate (i.e. no FLPs are detected), it is able to determine the speed of the link based on either 100M MLT-3 symbols or 10M Normal Link Pulses. In this case the link is presumed to be half-duplex per the IEEE standard. This ability is known as “Parallel Detection. This feature ensures interoperability with legacy link partners. If a link is formed via parallel detection, then bit 0 in register 6 is cleared to indicate that the Link Partner is not capable of auto-negotiation. The Ethernet MAC has access to this information via the management interface. If a fault occurs during parallel detection, bit 4 of register 6 is set.

Register 5 is used to store the Link Partner Ability information, which is coded in the received FLPs. If the Link Partner is not auto-negotiation capable, then register 5 is updated after completion of parallel detection to reflect the speed capability of the Link Partner.

5.6.6.1 Re-starting Auto-negotiation

Auto-negotiation can be re-started at any time by setting register 0, bit 9. Auto-negotiation will also re-start if the link is broken at any time. A broken link is caused by signal loss. This may occur because of a cable break, or because of an interruption in the signal transmitted by the Link Partner. Auto-negotiation resumes in an attempt to determine the new link configuration.

If the management entity re-starts Auto-negotiation by writing to bit 9 of the control register, the device will respond by stopping all transmission/receiving operations. Once the break_link_timer is done, in the Auto-negotiation state-machine (approximately 1200 mS) the auto-negotiation will re-start. The Link Partner will have also dropped the link due to lack of a received signal, so it too will resume auto-negotiation.

5.6.6.2 Disabling Auto-negotiation

Auto-negotiation can be disabled by setting register 0, bit 12 to zero. The device will then force its speed of operation to reflect the information in register 0, bit 13 (speed) and register 0, bit 8 (duplex). The speed and duplex bits in register 0 should be ignored when auto-negotiation is enabled.

5.6.6.3 Half vs. Full-Duplex

Half-duplex operation relies on the CSMA/CD (Carrier Sense Multiple Access / Collision Detect) protocol to handle network traffic and collisions. In this mode, the internal carrier sense signal, CRS, responds to both transmit and receive activity. In this mode, if data is received while the PHY is transmitting, a collision results.

In full-duplex mode, the PHY is able to transmit and receive data simultaneously. In this mode, the internal CRS responds only to receive activity. The CSMA/CD protocol does not apply and collision detection is disabled.

[Table 5-56](#) describes the behavior of the internal CRS bit under all receive/transmit conditions.

The internal CRS signal is used to trigger bit 10 (No Carrier) of the TX Status Word (See [Section 5.4.2.6, "TX Status Format," on page 50](#)). The CRS value, and subsequently the No Carrier value, are invalid during any full-duplex transmission. Therefore, these signals cannot be used as a verification method of transmitted packets when transmitting in 10/100 Mbps full-duplex modes.

TABLE 5-56: CRS BEHAVIOR

| Mode | Speed | Duplex | Activity | CRS Behavior (Note 5-1) |
|------------------|----------|-------------|--------------|--|
| Manual | 10 Mbps | Half-Duplex | Transmitting | Active |
| Manual | 10 Mbps | Half-Duplex | Receiving | Active |
| Manual | 10 Mbps | Full-Duplex | Transmitting | Low |
| Manual | 10 Mbps | Full-Duplex | Receiving | Active |
| Manual | 100 Mbps | Half-Duplex | Transmitting | Active |
| Manual | 100 Mbps | Half-Duplex | Receiving | Active |
| Manual | 100 Mbps | Full-Duplex | Transmitting | Low |
| Manual | 100 Mbps | Full-Duplex | Receiving | Active |
| Auto-Negotiation | 10 Mbps | Half-Duplex | Transmitting | Active |
| Auto-Negotiation | 10 Mbps | Half-Duplex | Receiving | Active |
| Auto-Negotiation | 10 Mbps | Full-Duplex | Transmitting | Low |
| Auto-Negotiation | 10 Mbps | Full-Duplex | Receiving | Active |
| Auto-Negotiation | 100 Mbps | Half-Duplex | Transmitting | Active |
| Auto-Negotiation | 100 Mbps | Half-Duplex | Receiving | Active |
| Auto-Negotiation | 100 Mbps | Full-Duplex | Transmitting | Low |
| Auto-Negotiation | 100 Mbps | Full-Duplex | Receiving | Active |

Note 5-1 The device's 10/100 PHY internal CRS signal operates in two modes: Active and Low. When in Active mode, the internal CRS will transition high and low upon line activity, where a high value indicates a carrier has been detected. In Low mode, the internal CRS stays low and does not indicate carrier detection. The internal CRS signal and No Carrier (bit 10 of the TX Status Word) cannot be used as a verification method of transmitted packets when transmitting in 10/100 Mbps full-duplex mode.

5.6.7 HP AUTO-MDIX

HP Auto-MDIX facilitates the use of CAT-3 (10 BASE-T) or CAT-5 (100 BASE-T) media UTP interconnect cable without consideration of interface wiring scheme. If a user plugs in either a direct connect LAN cable, or a cross-over patch cable, as shown in [Figure 5-19](#), the device's Auto-MDIX PHY is capable of configuring the TPO and TPI twisted pair pins for correct transceiver operation.

The internal logic of the device detects the TX and RX pins of the connecting device. Since the RX and TX line pairs are interchangeable, special PCB design considerations are needed to accommodate the symmetrical magnetics and termination of an Auto-MDIX design.

The Auto-MDIX function can be disabled through the [Special Control/Status Indications Register](#), or the external AUTOMDIX_EN configuration strap.

Note: When operating in 10BASE-T or 100BASE-TX manual modes, the Auto-MDIX crossover time can be extended via the [Extend Manual 10/100 Auto-MDIX Crossover Time](#) bit of the [EDPD NLP / Crossover Time Configuration Register](#). Refer to [Section 7.5.8, "EDPD NLP / Crossover Time Configuration Register,"](#) on [page 182](#) for additional information.

FIGURE 5-19: DIRECT CABLE CONNECTION VS. CROSS-OVER CABLE CONNECTION.

5.6.8 PHY POWER-DOWN MODES

There are 2 power-down modes for the PHY as discussed in the following sections.

5.6.8.1 General Power-Down

This power-down is controlled by register 0, bit 11. In this mode the PHY, except the management interface, is powered-down and stays in that condition as long as PHY register bit 0.11 is HIGH. When bit 0.11 is cleared, the PHY powers up and is automatically reset. Please refer to [Section 7.5.1, "Basic Control Register,"](#) on [page 175](#) for additional information on this register.

Note: For maximum power savings, auto-negotiation should be disabled before enabling the General Power-Down mode.

LAN950x

5.6.8.2 Energy Detect Power-Down (EDPD)

This power-down mode is activated by setting the [EDPWRDOWN](#) bit of the [Mode Control/Status Register](#). In this mode, when no energy is present on the line, the PHY is powered down (except the for the management interface, the SQUELCH circuit, and the ENERGYON logic). The ENERGYON logic is used to detect the presence of valid energy from 100BASE-TX, 10BASE-T, or Auto-negotiation signals.

In this mode, when the [ENERGYON](#) bit of the [Mode Control/Status Register](#) is low, the PHY is powered-down and nothing is transmitted. When energy is received via link pulses or packets, the [ENERGYON](#) bit goes high and the PHY powers-up. The PHY automatically resets itself into the state prior to power-down and asserts the [INT7](#) bit of the [PHY Interrupt Source Flag Register](#). If the ENERGYON interrupt is enabled, this event will cause a PHY interrupt to the Interrupt Controller and the power management event detection logic. The first and possibly the second packet to activate ENERGYON may be lost.

When THE [EDPWRDOWN](#) bit of the [Mode Control/Status Register](#) is low, energy detect power-down is disabled.

When in EDPD mode, the device's NLP characteristics may be modified. The device can be configured to transmit NLPs in EDPD via the [EDPD TX NLP Enable](#) bit of the [EDPD NLP / Crossover Time Configuration Register](#). When enabled, the TX NLP time interval is configurable via the [EDPD TX NLP Interval Timer Select](#) field of the [EDPD NLP / Crossover Time Configuration Register](#). When in EDPD mode, the device can also be configured to wake on the reception of one or two NLPs. Setting the [EDPD RX Single NLP Wake Enable](#) bit of the [EDPD NLP / Crossover Time Configuration Register](#) will enable the device to wake on reception of a single NLP. If the [EDPD RX Single NLP Wake Enable](#) bit is cleared, the maximum interval for detecting reception of two NLPs to wake from EDPD is configurable via the [EDPD RX NLP Max Interval Detect Select](#) field of the [EDPD NLP / Crossover Time Configuration Register](#).

5.6.9 PHY RESETS

In addition to a chip-level reset, the PHY supports two software-initiated resets. These are discussed in the following sections.

5.6.9.1 PHY Soft Reset via PMT_CTL Register PHY Reset (PHY_RST) Bit

The PHY soft reset is initiated by writing a '1' to the [PHY Reset \(PHY_RST\)](#) bit of the [Power Management Control Register \(PMT_CTL\)](#). This self-clearing bit will return to '0' after approximately 2ms, at which time the PHY reset is complete.

5.6.9.2 PHY Soft Reset via PHY Basic Control Register Bit 15 (PHY Reg. 0.15)

The PHY Reg. 0.15 Soft Reset is initiated by writing a '1' to bit 15 of the PHY's Basic Control Register. This self-clearing bit will return to '0' after approximately 256μs, at which time the PHY reset is complete. The BCR reset initializes the logic within the PHY, with the exception of register bits marked as NASR (Not Affected by Software Reset).

5.6.10 REQUIRED ETHERNET MAGNETICS

The magnetics selected for use with the device should be an Auto-MDIX style magnetic available from several vendors. The user is urged to review Application Note 8.13 "Suggested Magnetics" for the latest qualified and suggested magnetics. Vendors and part numbers are provided in this application note.

5.6.11 PHY REGISTERS

Please refer to [Section 7.5, "PHY Registers," on page 174](#) for a complete description of the PHY registers.

5.7 EEPROM Controller (EPC)

The device may use an external EEPROM to store the default values for the USB descriptors and the MAC address. The EEPROM controller supports most "93C46" type EEPROMs. The [EEP_SIZE](#) strap selects the size of the EEPROM attached to the device. When this strap is set to "0", a 128 byte EEPROM is attached and a total of seven address bits are used. When this strap is set to "1" a 256/512 byte EEPROM is attached and a total of nine address bits are used.

| |
|--|
| Note: A 3-wire style 1K/2K/4K EEPROM that is organized for 128 x 8-bit or 256/512 x 8-bit operation must be used. |
|--|

The MAC address is used as the default Ethernet MAC address and is loaded into the MAC's ADDRH and ADDRL registers. If a properly configured EEPROM is not detected, it is the responsibility of the Host LAN Driver to set the IEEE addresses.

After a system-level reset occurs, the device will load the default values from a properly configured EEPROM. The device will not accept USB transactions from the Host until this process is completed.

The EEPROM controller also allows the Host system to read, write and erase the contents of the Serial EEPROM.

5.7.1 EEPROM FORMAT

Table 5-57 illustrates the format in which data is stored inside of the EEPROM.

Note the EEPROM offsets are given in units of 16-bit word offsets. A length field with a value of zero indicates that the field does not exist in the EEPROM. The device will use the field's HW default value in this case.

Note 1: For the device descriptor, the only valid values for the length are 0 and 18.

2: For the configuration and interface descriptor, the only valid values for the length are 0 and 18.

3: The EEPROM programmer must ensure that if a string descriptor does not exist in the EEPROM, the referencing descriptor must contain 00h for the respective string index field.

4: If all string descriptor lengths are zero, then a Language ID will not be supported.

TABLE 5-57: EEPROM FORMAT

| EEPROM Address | EEPROM Contents |
|----------------|--|
| 00h | 0xA5 |
| 01h | MAC Address [7:0] |
| 02h | MAC Address [15:8] |
| 03h | MAC Address [23:16] |

LAN950x

TABLE 5-57: EEPROM FORMAT (CONTINUED)

| EEPROM Address | EEPROM Contents |
|----------------|--|
| 1Dh | Full-Speed Configuration and Interface Descriptor Word Offset |
| 1Eh | (LAN9500A/LAN9500Ai ONLY) LSB of GPIO Wake 0-10 (GPIOWK_n) field of General Purpose IO Wake Enable and Polarity Register (GPIO_WAKE) |
| 1Fh | (LAN9500A/LAN9500Ai ONLY) MSB of GPIO Wake 0-10 (GPIOWK_n) field of General Purpose IO Wake Enable and Polarity Register (GPIO_WAKE) |
| 20h | (LAN9500A/LAN9500Ai ONLY) GPIO PME Flags |

- Note 1:** The descriptor type for the device descriptors specified in the EEPROM is a don't care and always overwritten by HW to 0x1.
The descriptor size for the device descriptors specified in the EEPROM is a don't care and always overwritten by HW to 0x12.
The descriptor type for the configuration descriptors specified in the EEPROM is a don't care and always overwritten by HW to 0x2.
- 2:** Descriptors specified in EEPROM having `bcdUSB`, `bMaxPacketSize0`, and `bNumConfigurations` fields defined with values other than 0200h, 40h, and 1, respectively, will result in unwanted behavior and untoward results.
- 3:** EEPROM byte addresses past the indicated address can be used to store data for any purpose:
(LAN9500/LAN9500i ONLY): 1Dh
(LAN9500A/LAN9500Ai ONLY): 20h

[Table 5-58](#) describes the configuration flags. The configuration flags override the affects of the `RMT_WKP` and `PWR_SEL` straps. If a configuration descriptor exists in the EEPROM it will override both the configuration flags and associated straps.

TABLE 5-58: CONFIGURATION FLAGS

| Bits | Description |
|------|--|
| 7:6 | RESERVED |
| 5:4 | (LAN9500A/LAN9500Ai ONLY, Otherwise RESERVED) PHY Boost Refer to the PHY Boost (PHY_BOOST) field of the Hardware Configuration Register (HW_CFG) on page 122 for permissible field values. |
| 3 | RESERVED |
| 2 | Remote Wakeup Support 0 = The device does not support remote wakeup. 1 = The device supports remote wakeup. |
| 1 | (LAN9500A/LAN9500Ai ONLY, Otherwise RESERVED) LED Select Refer to the LED Select (LED_SEL) bit of the LED General Purpose IO Configuration Register (LED_GPIO_CFG) on page 129 for bit function definitions. |
| 0 | Power Method 0 = The device is bus powered. 1 = The device is self powered. |

[Table 5-59](#) describes the GPIO PME flags (LAN9500A/LAN9500Ai ONLY).

TABLE 5-59: GPIO PME FLAGS

| Bits | Description |
|------|--|
| 7 | <p>GPIO PME Enable Setting this bit enables the assertion of the GPIO0 or GPIO8 pin, as a result of a Wakeup (GPIO) pin, Magic Packet, or PHY Link Up. The host processor may use the GPIO0/GPIO8 pin to asynchronously wake up, in a manner analogous to a PCI PME pin. GPIO0 signals the event when operating in Internal PHY mode, while GPIO8 signals the event when operating in External PHY mode. Internal or External PHY mode of operation is dictated by the PHY_SEL pin.</p> <p>0 = The device does not support GPIO PME signaling. 1 = The device supports GPIO PME signaling.</p> <p>Note: When this bit is 0, the remaining GPIO PME parameters in this flag byte are ignored.</p> |
| 6 | <p>GPIO PME Configuration This bit selects whether the GPIO PME is signaled on the GPIO pin as a level or a pulse. If pulse is selected, the duration of the pulse is determined by the setting of the GPIO PME Length bit of this flag byte. The level of the signal or the polarity of the pulse is determined by the GPIO PME Polarity bit of this flag byte.</p> <p>0 = GPIO PME is signaled via a level. 1 = GPIO PME is signaled via a pulse.</p> <p>Note: If GPIO PME Enable is 0, this bit is ignored.</p> |
| 5 | <p>GPIO PME Length When the GPIO PME Configuration bit of this flag byte indicates that the GPIO PME is signaled by a pulse on the GPIO pin, this bit determines the duration of the pulse.</p> <p>0 = GPIO PME pulse length is 1.5 mS. 1 = GPIO PME pulse length is 150 mS.</p> <p>Note: If GPIO PME Enable is 0, this bit is ignored.</p> |
| 4 | <p>GPIO PME Polarity Specifies the level of the signal or the polarity of the pulse used for GPIO PME signaling.</p> <p>0 = GPIO PME signaling polarity is low. 1 = GPIO PME signaling polarity is high.</p> <p>Note: If GPIO PME Enable is 0, this bit is ignored.</p> |
| 3 | <p>GPIO PME Buffer Type This bit selects the output buffer type for GPIO0/GPIO8.</p> <p>0 = Open drain driver / open source 1 = Push-Pull driver</p> <p>Note 1: Buffer Type = 0, Polarity = 0 implies Open Drain Buffer Type = 0, Polarity = 1 implies Open Source</p> <p>2: If GPIO PME Enable is 0, this bit is ignored.</p> |
| 2 | <p>GPIO PME WOL Select Three types of wakeup events are supported; Magic Packet, PHY Link Up, and Wakeup Pin(s) assertion. Wakeup Pin(s) are selected via the GPIO Wake 0-10 (GPIOWK_n) field of the General Purpose IO Wake Enable and Polarity Register (GPIO_WAKE). The Wakeup Enables are specified in bytes 1Eh and 1Fh of the EEPROM. This bit selects whether Magic packet or Link Up wakeup events are supported.</p> <p>0 = Magic packet wakeup supported. 1 = PHY linkup wakeup supported. (not supported in External PHY mode)</p> <p>Note: If GPIO PME Enable is 0, this bit is ignored.</p> |
| 1 | <p>GPIO10 Detection Select This bit selects the detection mode for GPIO10 when operating in PME mode. In PME mode, GPIO10 is usable in both Internal and External PHY mode as a wakeup pin. This parameter defines whether the wakeup should occur on an active high or active low signal.</p> <p>0 = Active-low detection for GPIO10. 1 = Active-high detection for GPIO10.</p> <p>Note: If GPIO PME Enable is 0, this bit is ignored.</p> |
| 0 | RESERVED |

LAN950x

5.7.2 EEPROM DEFAULTS

The signature value of 0xA5 is stored at address 0. A different signature value indicates to the EEPROM controller that no EEPROM or an un-programmed EEPROM is attached to the device. In this case, the hardware default values are used, as shown in [Table 5-60](#). Please refer to [Section 5.3.1.6, "USB Descriptors," on page 31](#) for further information about the default USB values.

TABLE 5-60: EEPROM DEFAULTS

| Field | Default Value |
|-------------------------------------|--------------------------|
| MAC Address | FFFFFFFFFFFFh |
| Full-Speed Polling Interval (mS) | 01h |
| Hi-Speed Polling Interval (mS) | 04h |
| Configuration Flags | 04h |
| Maximum Power (mA) | FAh |
| Vendor ID | 0424h |
| Product ID | Note 5-2 |

Note 5-2 Product IDs are:

| Product | ID |
|--------------------|-------|
| LAN9500/LAN9500i | 9500h |
| LAN9500A/LAN9500Ai | 9E00h |

Note 1: The [Configuration Flags](#) are affected by the PWR_SEL and RMT_WKP straps.

2: Refer to the LAN950x Vendor/Product ID application note for details on proper usage of these fields.

5.7.3 EEPROM AUTO-LOAD

Certain system level resets (USB reset, POR, nRESET, and SRST) cause the EEPROM contents to be loaded into the device. After a reset, the EEPROM controller attempts to read the first byte of data from the EEPROM. If the value 0xA5 is read from the first address, then the EEPROM controller will assume that an external Serial EEPROM is present.

Note: The USB reset only loads the MAC address.

The EEPROM Controller will then load the entire contents of the EEPROM into an internal 512 byte SRAM. The contents of the SRAM are accessed by the CTL (USB Control Block) as needed (I.E. to fill Get Descriptor commands). A detailed explanation of the EEPROM byte ordering with respect to the MAC address is given in [Section 7.4.3, "MAC Address Low Register \(ADDR_L\)," on page 163](#).

If an 0xA5h is not read from the first address, the EEPROM controller will end initialization. The default values, as specified in [Table 5-60](#), will then be assumed by the associated registers. It is then the responsibility of the Host LAN driver software to set the IEEE address by writing to the MAC's ADDR_H and ADDR_L registers.

The device may not respond to the USB Host until the EEPROM loading sequence has completed. Therefore, after reset, the USB PHY is kept in the disconnect state until the EEPROM load has completed.

5.7.4 EEPROM HOST OPERATIONS

After the EEPROM controller has finished reading (or attempting to read) the EEPROM after a system-level reset, the Host is free to perform other EEPROM operations. EEPROM operations are performed using the EEPROM Command (E2P_CMD) and EEPROM Data (E2P_DATA) registers. [Section 7.3.12, "EEPROM Command Register \(E2P_CMD\)," on page 136](#) provides an explanation of the supported EEPROM operations.

If the EEPROM operation is the “write location” (WRITE) or “write all” (WRAL) commands, the Host must first write the desired data into the E2P_DATA register. The Host must then issue the WRITE or WRAL command using the E2P_CMD register by setting the EPC_CMD field appropriately. If the operation is a WRITE, the EPC_ADDR field in E2P_CMD must also be set to the desired location. The command is executed when the Host sets the EPC_BSY bit high. The completion of the operation is indicated when the EPC_BSY bit is cleared.

If the EEPROM operation is the “read location” (READ) operation, the Host must issue the READ command using the E2P_CMD register with the EPC_ADDR set to the desired location. The command is executed when the Host sets the EPC_BSY bit high. The completion of the operation is indicated when the EPC_BSY bit is cleared, at which time the data from the EEPROM may be read from the E2P_DATA register.

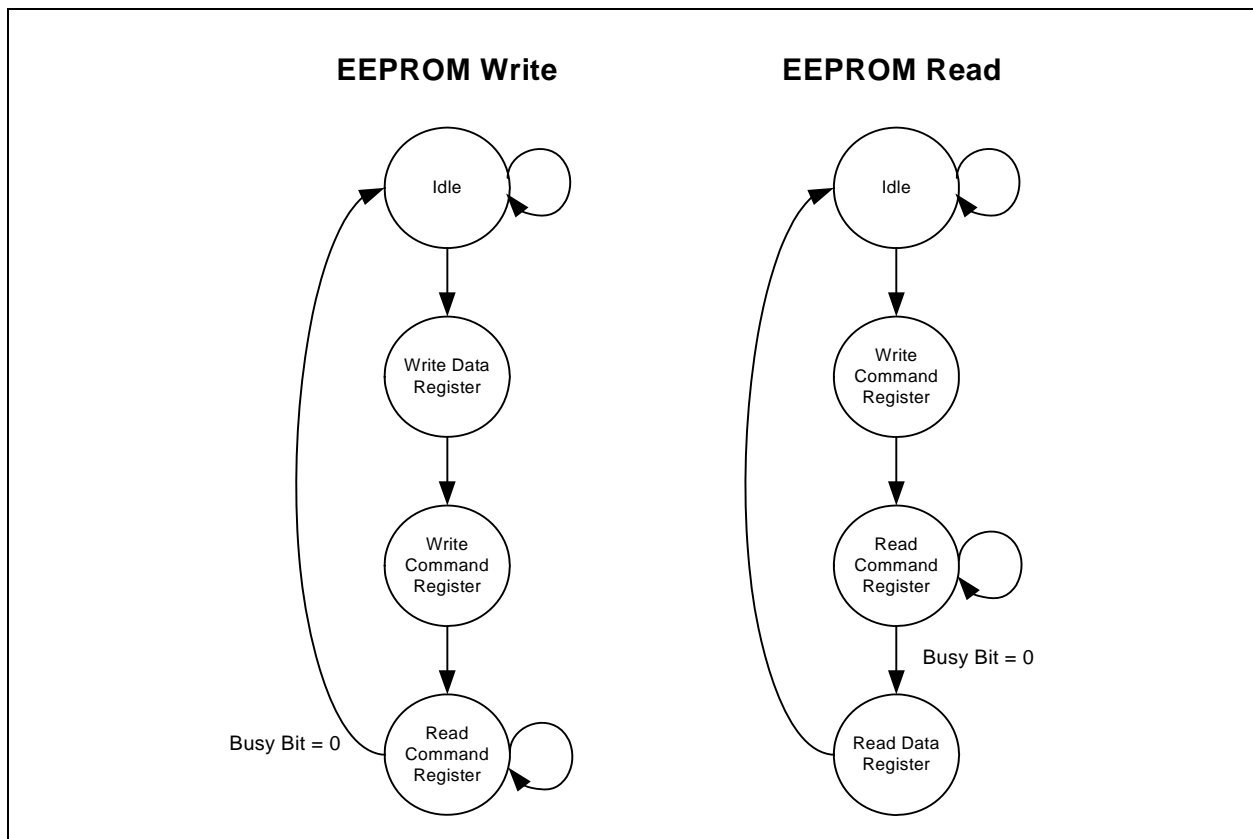

Other EEPROM operations are performed by writing the appropriate command to the E2P_CMD register. The command is executed when the Host sets the EPC_BSY bit high. The completion of the operation is indicated when the EPC_BSY bit is cleared. In all cases, the Host must wait for EPC_BSY to clear before modifying the E2P_CMD register.

Note: The EEPROM device powers-up in the erase/write disabled state. To modify the contents of the EEPROM, the Host must first issue the EWEN command.

If an operation is attempted, and an EEPROM device does not respond within 30mS, the device will timeout, and the EPC Time-out bit (EPC_TO) in the E2P_CMD register will be set.

Figure 5-20 illustrates the Host accesses required to perform an EEPROM Read or Write operation.

FIGURE 5-20: EEPROM ACCESS FLOW DIAGRAM

LAN950x

5.7.4.1 Supported EEPROM Operations

The EEPROM controller supports the following EEPROM operations under Host control via the E2P_CMD register. The operations are commonly supported by “93C46” EEPROM devices. A description and functional timing diagram is provided below for each operation. Please refer to the E2P_CMD register description in [Section 7.3.12, "EEPROM Command Register \(E2P_CMD\)," on page 136](#) for E2P_CMD field settings for each command.

ERASE (Erase Location): If erase/write operations are enabled in the EEPROM, this command will erase the location selected by the EPC Address field (EPC_ADDR). The EPC_TO bit is set if the EEPROM does not respond within 30mS.

FIGURE 5-21: EEPROM ERASE CYCLE

ERAL (Erase All): If erase/write operations are enabled in the EEPROM, this command will initiate a bulk erase of the entire EEPROM. The EPC_TO bit is set if the EEPROM does not respond within 30mS.

FIGURE 5-22: EEPROM ERAL CYCLE

EWDS (Erase/Write Disable): After issued, the EEPROM will ignore erase and write commands. To re-enable erase/write operations issue the EWEN command.

FIGURE 5-23: EEPROM EWDS CYCLE

EWEN (Erase/Write Enable): Enables the EEPROM for erase and write operations. The EEPROM will allow erase and write operations until the “Erase/Write Disable” command is sent, or until power is cycled.

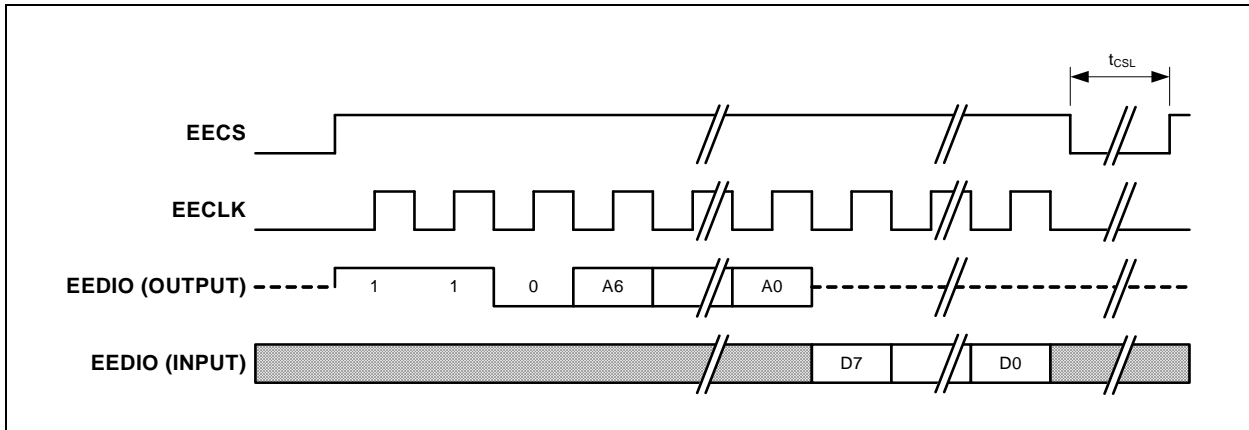

Note: The EEPROM device will power-up in the erase/write-disabled state. Any erase or write operations will fail until an Erase/Write Enable command is issued.

FIGURE 5-24: EEPROM EWEN CYCLE

READ (Read Location): This command will cause a read of the EEPROM location pointed to by EPC Address (EPC_ADDR). The result of the read is available in the E2P_DATA register.

FIGURE 5-25: EEPROM READ CYCLE

WRITE (Write Location): If erase/write operations are enabled in the EEPROM, this command will cause the contents of the E2P_DATA register to be written to the EEPROM location selected by the EPC Address field (EPC_ADDR). The EPC_TO bit is set if the EEPROM does not respond within 30mS.

FIGURE 5-26: EEPROM WRITE CYCLE

WRAL (Write All): If erase/write operations are enabled in the EEPROM, this command will cause the contents of the E2P_DATA register to be written to every EEPROM memory location. The EPC_TO bit is set if the EEPROM does not respond within 30mS.

FIGURE 5-27: EEPROM WRAL CYCLE

Table 5-61, "Required EECLK Cycles", shown below, shows the number of EECLK cycles required for each EEPROM operation.

TABLE 5-61: REQUIRED EECLK CYCLES

| Operation | Required EECLK Cycles |
|-----------|-----------------------|
| ERASE | 10 |
| ERAL | 10 |
| EWDS | 10 |
| EWEN | 10 |
| READ | 18 |
| WRITE | 18 |
| WRAL | 18 |

5.7.4.2 Host Initiated EEPROM Reload

The Host can initiate a reload of the EEPROM by issuing the RELOAD command via the E2P Command (E2P_CMD) register. If the first byte read from the EEPROM is not 0xA5, it is assumed that the EEPROM is not present, or not programmed, and the reload will fail. The Data Loaded bit of the E2P_CMD register indicates a successful reload of the EEPROM.

Note: It is not recommended that the RELOAD command be used as part of normal operation, as race conditions can occur with USB Commands that access descriptor data. It is best for the Host to issue a SRST to reload the EEPROM data.

5.7.4.3 EEPROM Command and Data Registers

Refer to [Section 7.3.12, "EEPROM Command Register \(E2P_CMD\)," on page 136](#) and [Section 7.3.13, "EEPROM Data Register \(E2P_DATA\)," on page 139](#) for a detailed description of these registers. Supported EEPROM operations are described in these sections.

5.7.4.4 EEPROM Timing

Refer to [Section 8.5.4, "EEPROM Timing," on page 198](#) for detailed EEPROM timing specifications.

LAN950x

5.7.5 EXAMPLES OF EEPROM FORMAT INTERPRETATION

5.7.5.1 LAN9500/LAN9500i

Table 5-62 and Table 5-63 provide an example of how the contents of a EEPROM are formatted in the case of LAN9500/LAN9500i. Table 5-62 is a dump of the EEPROM memory (256-byte EEPROM), while Table 5-63 illustrates, byte by byte, how the EEPROM is formatted.

TABLE 5-62: DUMP OF EEPROM MEMORY - LAN9500/LAN9500I

| Offset Byte | Value |
|---------------|-------------------------|
| 0000h | A5 12 34 56 78 9A BC 01 |

5.8 Customized Operation Without EEPROM

Customized operation without EEPROM is supported only by LAN9500A/LAN9500Ai.

The device provides the capability to customize operation without the use of an EEPROM. Descriptor information and initialization quantities normally fetched from EEPROM and used to initialize descriptors and elements of the [System Control and Status Registers](#) may be specified via an alternate mechanism. This alternate mechanism involves the use of the Descriptor RAM in conjunction with the Attribute Registers and select elements of the [System Control and Status Registers](#). The software device driver orchestrates the process by performing the following actions in the order indicated:

- [Initialization of SCSR Elements in Lieu of EEPROM Load](#)
- [Attribute Register Initialization](#)
- [Descriptor RAM Initialization](#)
- [Enable Descriptor RAM and Flag Attribute Registers as Source](#)
- [Inhibit Reset of Select SCSR Elements](#)

The following subsections explain these actions. The attribute registers must be written prior to initializing the Descriptor RAM. Failure to do this will prevent the PWR_SEL and RMT_WKUP flags from being overwritten by the bmAttributes of the Configuration Descriptor.

5.8.1 INITIALIZATION OF SCSR ELEMENTS IN LIEU OF EEPROM LOAD

During EEPROM operation, the following register fields are initialized by the hardware using the values contained in the EEPROM. In the absence of an EEPROM, the software device driver must initialize these quantities:

- [MAC Address High Register \(ADDRH\)](#) and [MAC Address Low Register \(ADDRL\)](#)
- [PHY Boost \(PHY_BOOST\)](#) field of [Hardware Configuration Register \(HW_CFG\)](#)
- [LED Select \(LED_SEL\)](#) bit of the [LED General Purpose IO Configuration Register \(LED_GPIO_CFG\)](#)
- [GPIO Wake 0-10 \(GPIOWKn\)](#) field of the [General Purpose IO Wake Enable and Polarity Register \(GPIO_WAKE\)](#)

5.8.2 ATTRIBUTE REGISTER INITIALIZATION

The Attribute Registers are as follows:

- [HS Descriptor Attributes Register \(HS_ATTR\)](#)
- [FS Descriptor Attributes Register \(FS_ATTR\)](#)
- [String Descriptor Attributes Register 0 \(STRNG_ATTR0\)](#)
- [String Descriptor Attributes Register 1 \(STRNG_ATTR1\)](#)
- [Flag Attributes Register \(FLAG_ATTR\)](#)

All of these registers, with the exception of FLAG_ATTR, contain fields defining the lengths of the descriptors written into the Descriptor RAM. If the descriptor is not written into the Descriptor RAM, the associated entry in the Attributes Register must be written as 0. Writing an erroneous or illegal length will result in untoward operation and unexpected results.

The [Flag Attributes Register \(FLAG_ATTR\)](#) provides the mechanism to initialize components of the Configuration Flags and GPIO PME Flags that are stand-alone and not part of any other System Control and Status Register. During EEPROM operation, the analogous fields in this register are read by the hardware from the EEPROM and are not available to the software for read-back or modification.

Note 1: The software device driver must initialize these registers prior to initializing the Descriptor RAM.

- 2:** The `bmAttributes` field of the HS and FS descriptors in descriptor RAM (if present) must be consistent with the contents of the [Flag Attributes Register \(FLAG_ATTR\)](#).

5.8.3 DESCRIPTOR RAM INITIALIZATION

The Descriptor RAM contents are initialized using the Data Port registers. The Data Port registers are used to select the Descriptor RAM and write the descriptor elements into it. The Descriptor RAM is 512 bytes in length. Every descriptor written into the Descriptor RAM must be DWORD aligned. The Attribute Registers discussed in [Section 5.8.2](#) must be written with the length of the descriptors written into the Descriptor RAM. If a descriptor is not used, hence not written into Descriptor RAM, its length must be written as 0 into the associated Attribute Register.

Note 1: The Attribute Registers must be initialized before the Descriptor RAM.

- 2:** Address 0 of the Descriptor RAM is always reserved for the Language ID descriptor, even if it will not be supported.

The descriptors must be written in the following order, starting at address 0 of the RAM and observing the DWORD alignment rule:

- Language ID Descriptor
- Manufacturing String Descriptor (String Index 1)
- Product Name String Descriptor (String Index 2)
- Serial Number String Descriptor (String Index 3)
- Configuration String Descriptor (String Index 4)
- Interface String Descriptor (String Index 5)
- HS Device Descriptor
- HS Configuration Descriptor
- FS Device Descriptor
- FS Configuration Descriptor

An example of Descriptor RAM use is illustrated in [Figure 5-28](#).

As in the case of descriptors specified in EEPROM, the following restrictions apply to descriptors written into Descriptor RAM:

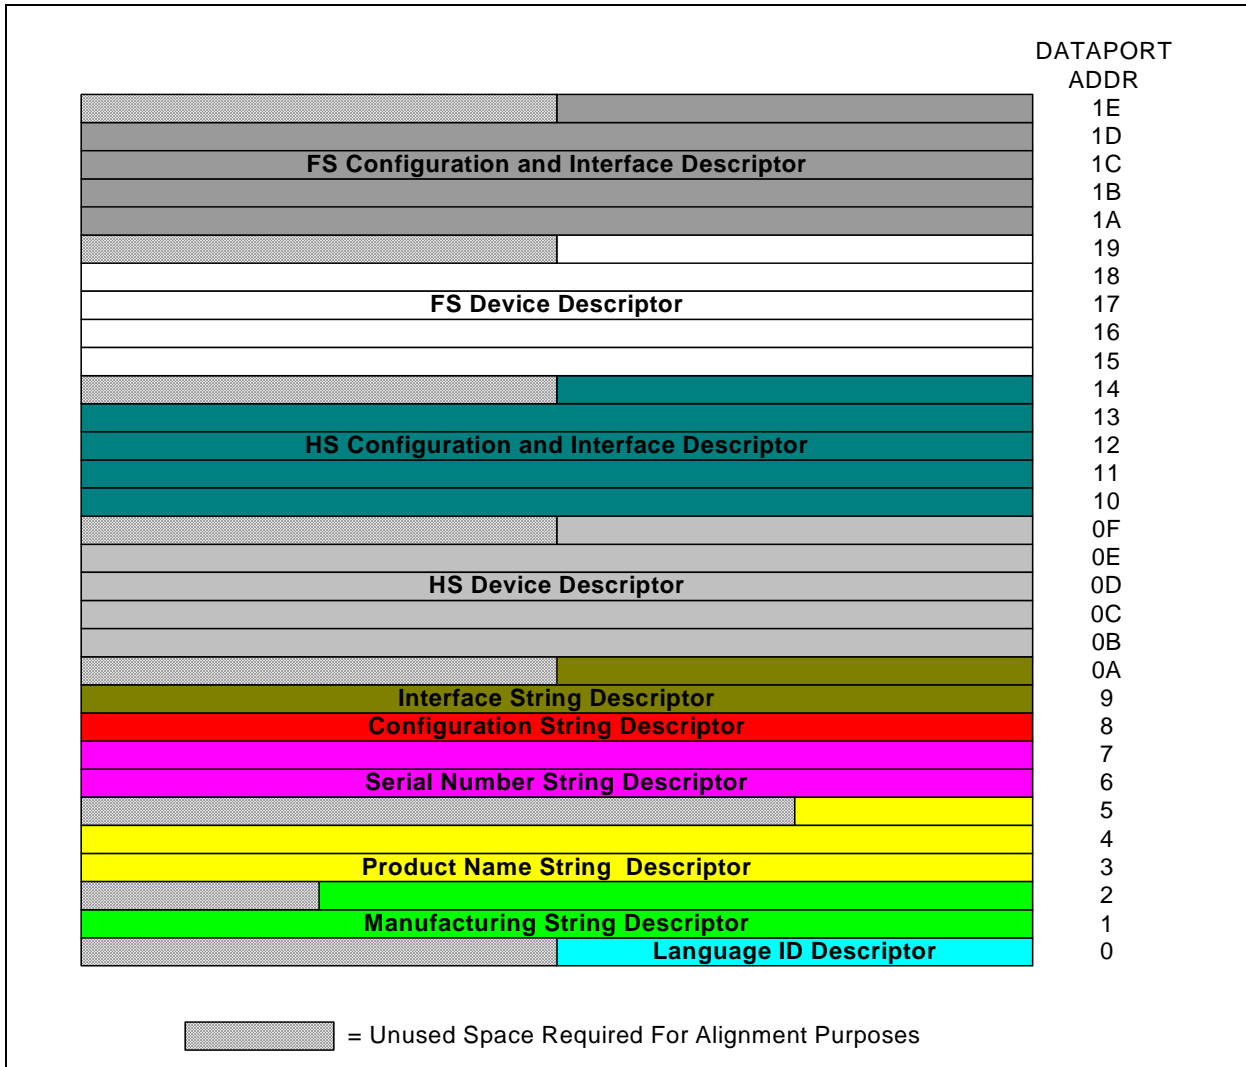

1. For Device Descriptors, the only valid values for the length are 0 and 18. The descriptor size for the Device Descriptors specified in the Descriptor RAM is a don't care and always overwritten by HW to 0x12 when transmitting the descriptor to the host.
2. The descriptor type for Device Descriptors specified in the Descriptor RAM is a don't care and is always overwritten by HW to 0x1 when transmitting the descriptor to the host.
3. For the Configuration and Interface descriptor, the only valid values for the length are 0 and 18. The descriptor size for the Device Descriptors specified in the Descriptor RAM is a don't care and always overwritten by HW to 0x12 when transmitting the descriptor to the host.
4. The descriptor type for the configuration descriptors specified in the Descriptor RAM is a don't care and always overwritten by HW to 0x2 when transmitting the descriptor to the host.
5. If a string descriptor does not exist in the Descriptor RAM, the referencing descriptor must contain 00h for the respective string index field.
6. If all string descriptor lengths are zero than a Language ID will not be supported.

Note 1: The first entry in the Descriptor RAM is always reserved for the Language ID descriptor, even if it will not be supported.

- 2:** Descriptors specified having `bcdUSB`, `bMaxPacketSize0`, and `bNumConfigurations` fields defined with values other than 0200h, 40h, and 1, respectively, will result in unwanted behavior and untoward results.

The [RAM Test Mode Enable \(TESTEN\)](#) bit must be deasserted after programming the descriptor RAM.

FIGURE 5-28: DESCRIPTOR RAM EXAMPLE

5.8.4 ENABLE DESCRIPTOR RAM AND FLAG ATTRIBUTE REGISTERS AS SOURCE

The [EEPROM Emulation Enable \(EEM\)](#) bit of the [Hardware Configuration Register \(HW_CFG\)](#) must be configured by the software device driver to use the Descriptor RAM and the Attribute Registers for custom operation. Upon assertion of [EEPROM Emulation Enable \(EEM\)](#), the hardware will utilize the Descriptor information contained in the Descriptor RAM, the Attributes Registers, and the values of the items listed in [Section 5.8.1](#) to facilitate custom operation.

5.8.5 INHIBIT RESET OF SELECT SCSR ELEMENTS

The software device driver must take care to ensure that the contents of the Descriptor RAM and SCSR register content critical to custom operation using Descriptor RAM are preserved across reset operations other than POR. The driver must configure the [Reset Protection \(RST_PROTECT\)](#) bit of the [Hardware Configuration Register \(HW_CFG\)](#) in order to accomplish this.

The following registers have contents that can be preserved across all resets other than POR. Consult the register's description for additional details.

- Descriptor RAM
- Attribute Registers

- MAC Address High Register (ADDRH) and MAC Address Low Register (ADDRL)
- Hardware Configuration Register (HW_CFG)
- LED General Purpose IO Configuration Register (LED_GPIO_CFG)
- General Purpose IO Wake Enable and Polarity Register (GPIO_WAKE)

5.9 Device Clocking

The device requires a fixed-frequency 25MHz clock source. This is typically provided by attaching a 25MHz crystal to the XI and XO pins. The clock can optionally be provided by driving the XI input pin with a single-ended 25MHz clock source. If a single-ended source is selected, the clock input must run continuously for normal device operation.

Internally, the device generates its required clocks with a phase-locked loop (PLL). It reduces its power consumption in several of its operating states by disabling its internal PLL and derivative clocks. The 25MHz clock remains operational in all states where power is applied.

5.10 Device Power Sources

The device may be soft powered by the USB bus or self powered via external power supplies. The following external 3.3V power supplies are required when power is not being furnished by the USB bus:

- VDD33IO, VDD33A

Note: The device also uses power supplied by an internal regulator and connection does not vary. Since the regulated supply is derived from VDD33IO, there is no need to discuss it separately.

5.11 Power States

The following power states are featured.

- UNPOWERED
- NORMAL (Unconfigured and Configured)
- Suspend (SUSPEND0, SUSPEND1, SUSPEND2, and SUSPEND3)

All four SUSPEND states are supported by LAN9500A/LAN9500Ai. SUSPEND3 is not supported by LAN9500/LAN9500i.

Figure 5-29 illustrates the power states and allowed state transitions.

FIGURE 5-29: POWER STATES

LAN950x

Note 1: It is not possible to transition from SUSPEND2 to NORMAL Configured if SUSPEND2 was entered via a transition from NORMAL Unconfigured.

2: When the device is bus powered, VBUS_DET is tied to 1b. Therefore, the UNPOWERED state only has meaning for self powered operation.

5.11.1 UNPOWERED STATE

The UNPOWERED state provides a mechanism for the device to conserve power when VBUS_DET is not connected and the device is self powered.

The device may initially enter the UNPOWERED state when a POR occurs and USB power is not detected. This state persists until the VBUS_DET is asserted. The UNPOWERED state is alternatively entered whenever VBUS_DET deasserts.

In order to make the LAN950x fully operational, the Host must configure the device, which places it in the NORMAL Configured state.

5.11.2 NORMAL STATE

The NORMAL state is the fully functional state of the device. There are two flavors of the NORMAL state, NORMAL Configured and NORMAL Unconfigured. In the Configured variation, all chip subsystem modules are enabled. The Unconfigured variation has only a subset of the modules enabled. The reduced functionality allows for power savings.

This NORMAL state is entered by any of the following methods.

- A system reset and VBUS_DET is asserted.
- The device is in the UNPOWERED state and VBUS_DET is asserted.
- The device is suspended and the Host issues resume signaling.
- The device is suspended and a wake event is detected.

5.11.2.1 Unconfigured

Upon initially entering the NORMAL state, the device is unconfigured. The device transitions to the NORMAL Configured state upon the Host completion of the USB configuration.

It is possible for the device to be deconfigured by the Host after being placed in the NORMAL configured state, via a set_configuration command. In this case, the CPM must place the device back into the NORMAL Unconfigured state.

5.11.2.2 Reset Operation

After a system reset, the device is placed into the NORMAL Unconfigured state. When in the NORMAL state, the READY bit in the [Power Management Control Register \(PMT_CTL\)](#) is set. This READY bit is useful to the Host after a USB reset occurs. In this case, it indicates that the values in the EEPROM have been completely loaded.

5.11.2.3 Suspend Operation

When returning to the NORMAL state from the SUSPEND state, the USB context is maintained. After entering the NORMAL state, the READY bit in the PMT_CTL register is asserted.

| |
|--|
| <p>Note: If the originating suspend state is SUSPEND2, the Host is required to reinitialize the Ethernet PHY registers.</p> |
|--|

5.11.3 SUSPEND STATES

The SUSPEND state is entered after the USB Host suspends the device. The LAN950x family features four ([Note 5-3](#)) variations of the USB SUSPEND state. Each state offers different options in terms of power consumption and wakeup support.

A SUSPEND state is entered via a transition from the NORMAL state. The SUSPEND_MODE field in the [Power Management Control Register \(PMT_CTL\)](#), indicates which SUSPEND state is to be used. The Host sets the value of this field to select the desired suspend state, then sends suspend signaling. A transfer back to the NORMAL state occurs when the Host sends resume signaling or a wakeup event is detected.

The device can be suspended from the NORMAL Unconfigured state. In this scenario, it is only possible to transition to the SUSPEND2 state. Subsequent resume signaling or a wakeup event will cause the device to transition back to the NORMAL Unconfigured state.

Note 5-3 All four SUSPEND states are supported by LAN9500A/LAN9500Ai. SUSPEND3 is not supported by LAN9500/LAN9500i.

Note: If the device is deconfigured, the SUSPEND_MODE field in the [Power Management Control Register \(PMT_CTL\)](#) resets to 10b.

5.11.3.1 Reset from Suspend

All suspend states must respond to a USB Reset and pin reset, nRESET. The application of these resets result in the device's hardware being re-initialized and placed into the NORMAL Unconfigured state.

5.11.3.2 SUSPEND0

This state is entered from the NORMAL state when the device is suspended and the SUSPEND_MODE field in the [Power Management Control Register \(PMT_CTL\)](#) is set to 00b.

Refer to [Section 5.12.2.1, "Enabling GPIO Wake Events," on page 106](#), [Section 5.12.2.2, "Enabling WOL Wake Events," on page 107](#), and [Section 5.12.2.4, "Enabling PHY Link Up Wake Events \(LAN9500A/LAN9500Ai ONLY\)," on page 108](#) for detailed instructions on how to program events that cause resumption from the SUSPEND0 state.

In this state, the MAC can optionally be programmed to detect a Wake-On-Lan event or Magic Packet event.

GPIO events can be programmed to cause wakeup in this state. For LAN9500A/LAN9500Ai only, if GPIO7 signals the event, the [PHY Link Up Enable \(PHY_LINKUP_EN\)](#) bit of the [General Purpose IO Wake Enable and Polarity Register \(GPIO_WAKE\)](#) may be examined to determine whether a PHY Link Up event or pin event occurred.

The Host may take the device out of the SUSPEND0 state at any time.

5.11.3.3 SUSPEND1

This state is entered from the NORMAL state when the device is suspended and the SUSPEND_MODE field in the [Power Management Control Register \(PMT_CTL\)](#) is set to 01b.

Refer to [Section 5.12.2.1, "Enabling GPIO Wake Events," on page 106](#), and [Section 5.12.2.3, "Enabling Link Status Change \(Energy Detect\) Wake Events," on page 107](#) for detailed instructions on how to program events that cause resumption from the SUSPEND1 state.

In this state, the Ethernet PHY can be optionally programmed for energy detect. GPIO events can also be programmed to cause wakeup in this state.

The Host may take the device out of the SUSPEND1 state at any time.

5.11.3.4 SUSPEND2

This state is entered from the NORMAL state when the device is suspended and the SUSPEND_MODE field in the [Power Management Control Register \(PMT_CTL\)](#) is set to 10b. SUSPEND2 is the default suspend mode.

Refer to [Section 5.12.2.1, "Enabling GPIO Wake Events," on page 106](#) for detailed instructions on how to program events that cause resumption from the SUSPEND2 state.

This state consumes the least amount of power. In this state, the device may only be awakened by the Host or GPIO assertion.

The state of the Ethernet PHY is lost when entering SUSPEND2. Therefore, Host must reinitialize the PHY after the device returns to the NORMAL state.

5.11.3.5 SUSPEND3 (Not Supported by LAN9500/LAN9500i)

This state is entered from the NORMAL state when the device is suspended and the SUSPEND_MODE field in the [Power Management Control Register \(PMT_CTL\)](#) is set to 11b.

Refer to [Section 5.12.2.1, "Enabling GPIO Wake Events," on page 106](#), [Section 5.12.2.4, "Enabling PHY Link Up Wake Events \(LAN9500A/LAN9500Ai ONLY\)," on page 108](#), and [Section 5.12.2.5, "Enabling "Good Frame" Wake Events \(LAN9500A/LAN9500Ai ONLY\)," on page 108](#) for detailed instructions on how to program events that cause resumption from the SUSPEND3 state.

In this suspend state, all clocks in the device are enabled and power consumption is similar to the NORMAL state. However, it allows for power savings in the Host CPU, which greatly exceeds that of the device. The driver may place the device in this state after prolonged periods of not receiving any Ethernet traffic.

LAN950x

This state supports wakeup from GPIO assertion, PHY Link Up, and on reception of a frame passing the filtering constraints set by the [MAC Control Register \(MAC_CR\)](#). Due to the limited amount of RX FIFO buffering, it is possible that there will be frames lost when in this state, as the USB resume time greatly exceeds the buffering capacity of the FIFO.

The Wake-On-LAN bit of the [Wakeup Status \(WUPS\)](#) field of the [Power Management Control Register \(PMT_CTL\)](#) is used to signal wakeup due to reception of a frame passing the aforementioned filtering constraints. This bit, along with the [GPIO \[10:0\] \(GPIOx_INT\)](#) bits of the [Interrupt Status Register \(INT_STS\)](#), may be examined to determine the event(s) causing the wakeup. If GPIO7 is found to have caused the wakeup, the [PHY Link Up Enable \(PHY_LINK_UP_EN\)](#) bit of the [General Purpose IO Wake Enable and Polarity Register \(GPIO_WAKE\)](#) may be examined to determine whether a PHY Link Up event or pin event occurred.

Note 1: Wake-On-LAN events **MUST NOT** be enabled in the [Wakeup Control and Status Register \(WUCSR\)](#) while operating in the SUSPEND3 state. If any Wake-On-LAN Event is enabled in WUCSR, all received frames will be dropped. The setting of the [Wake-On-Lan Enable \(WOL_EN\)](#) bit of the [Power Management Control Register \(PMT_CTL\)](#) is a “don’t care”.

2: The Wake-On-LAN bit of the [Wakeup Status \(WUPS\)](#) is used to signal both Wake-On-LAN events and wakeup from SUSPEND3 state due to reception of frames passing the filtering constraints set by the [MAC Control Register \(MAC_CR\)](#). In order to interpret the [Wakeup Status \(WUPS\)](#) without ambiguity, the software driver may examine the [Suspend Mode \(SUSPEND_MODE\)](#) field of the [Power Management Control Register \(PMT_CTL\)](#) to determine the suspend state it is coming out of.

5.12 Wake Events

The following events can wake up/enable the device, depending on the power state.

- USB Host Resume
- VBUS_DET assertion
- Wake On LAN (Wakeup Frame, Magic Packet, Perfect Destination Address Frame, and Broadcast Frame)
- Reception of a “Good Frame” - ([Note 5-4](#)) a frame received when no Wake-On-LAN events are enabled in the [Wakeup Control and Status Register \(WUCSR\)](#) that meets the filtering requirements configured in the [MAC Control Register \(MAC_CR\)](#).
- PHY Energy Detect
- PHY Link Up
- GPIO[10:0]

Note 5-4 Not Supported by LAN9500/LAN9500i.

[Table 5-66](#) illustrates the wake events permitted in each of the power states.

TABLE 5-66: POWER STATE/WAKE EVENT MAPPING

| Power State | USB Host Resume Signaling | VBUS_DET | WOL | Good Frame Note 5-5 | PHY Energy Detect | PHY Link Up | GPIO[10:0] |
|--------------------------------------|---------------------------|----------|-----|--|-------------------|-------------|------------|
| SUSPEND0 | YES | NO | YES | NO | NO | YES | YES |
| SUSPEND1 | YES | NO | NO | NO | YES | NO | YES |
| SUSPEND2 | YES | NO | NO | NO | NO | NO | YES |
| SUSPEND3 Note 5-5 | YES | NO | NO | YES | NO | YES | YES |
| UNPOWERED | NO | YES | NO | NO | NO | NO | NO |

Note 5-5 Not Supported by LAN9500/LAN9500i.

The occurrence of a GPIO wake event causes the corresponding bit in the [Interrupt Status Register \(INT_STS\)](#) to be set. Before suspending the device, the Host must ensure that any pending wake events are cleared. Otherwise, the device will immediately be awakened after being suspended.

5.12.1 DETECTING WAKEUP EVENTS

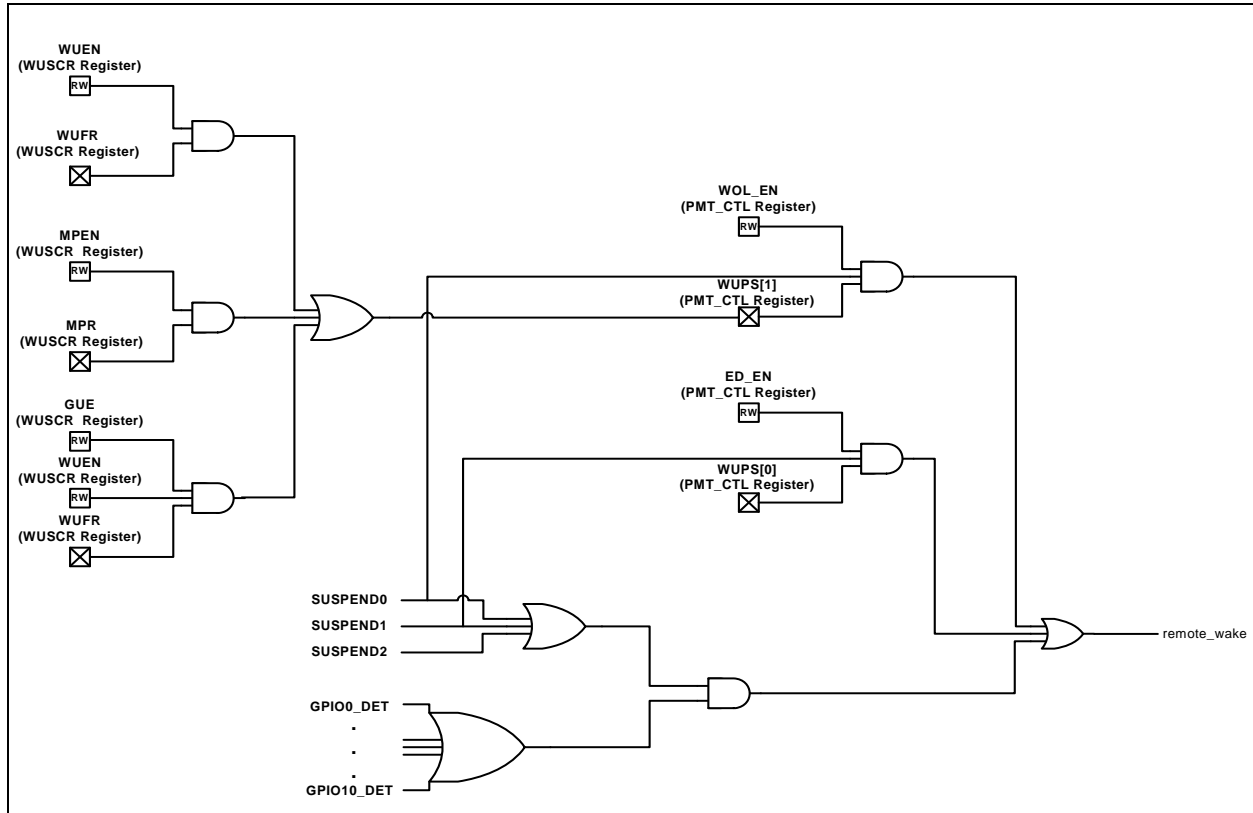

The wakeup detection logic for LAN9500A/LAN9500Ai is a super set of that of LAN9500/LAN9500i. All of these devices support the ability to generate remote wake events on detection of a GPIO event, WOL event, or Ethernet link status change (energy detect) as primitives. An extension of the WOL event class, to provide for Perfect DA Frame Received,

Broadcast Frame Received, and “Good Frame” Received, wake events, as well as provision for an additional wakeup event to signal PHY Link Up via GPIO7, is reflected in the LAN9500A/LAN9500Ai detection logic. The following sections illustrate and discuss the detection logic for all of the devices in the LAN950x family.

5.12.1.1 LAN9500/LAN9500i Wake Detection Logic

A simplified diagram of the wake event detection logic for LAN9500/LAN9500i is shown in [Figure 5-30](#).

FIGURE 5-30: WAKE EVENT DETECTION BLOCK DIAGRAM (LAN9500/LAN9500I)

Note: Diagram does not represent actual hardware implementation.

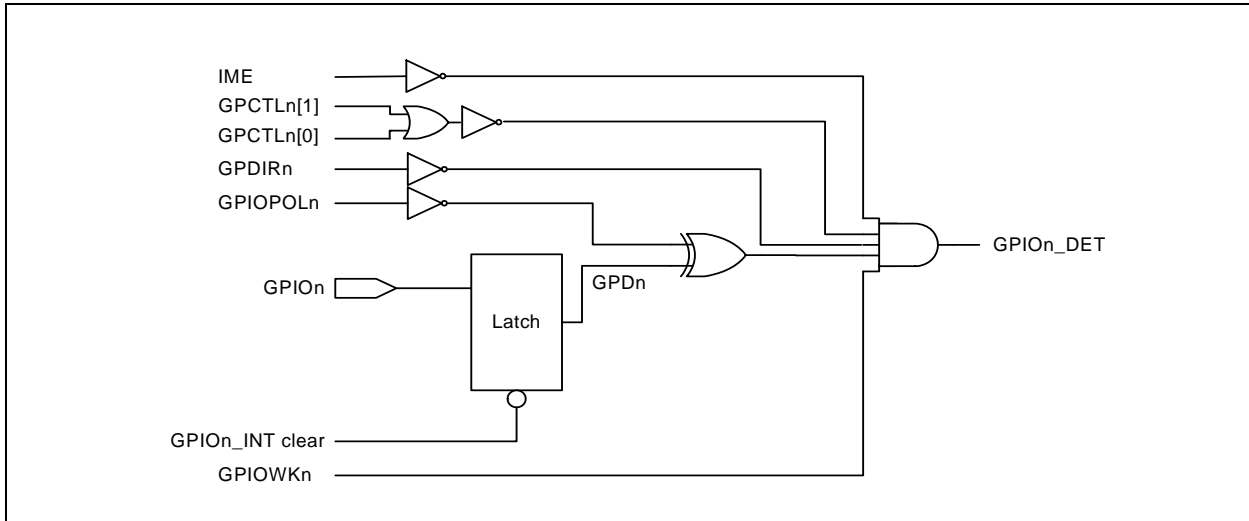

LAN950x

FIGURE 5-31: GPIOs 0-7 WAKE DETECTION LOGIC (LAN9500/LAN9500I)

Note: The IME bit is in the [Hardware Configuration Register \(HW_CFG\)](#). [General Purpose IO Configuration Register \(GPIO_CFG\)](#) and [General Purpose IO Wake Enable and Polarity Register \(GPIO_WAKE\)](#) must be set accordingly. Diagram does not represent actual hardware implementation.

FIGURE 5-32: GPIOs 8-10 WAKE DETECTION LOGIC (LAN9500/LAN9500I)

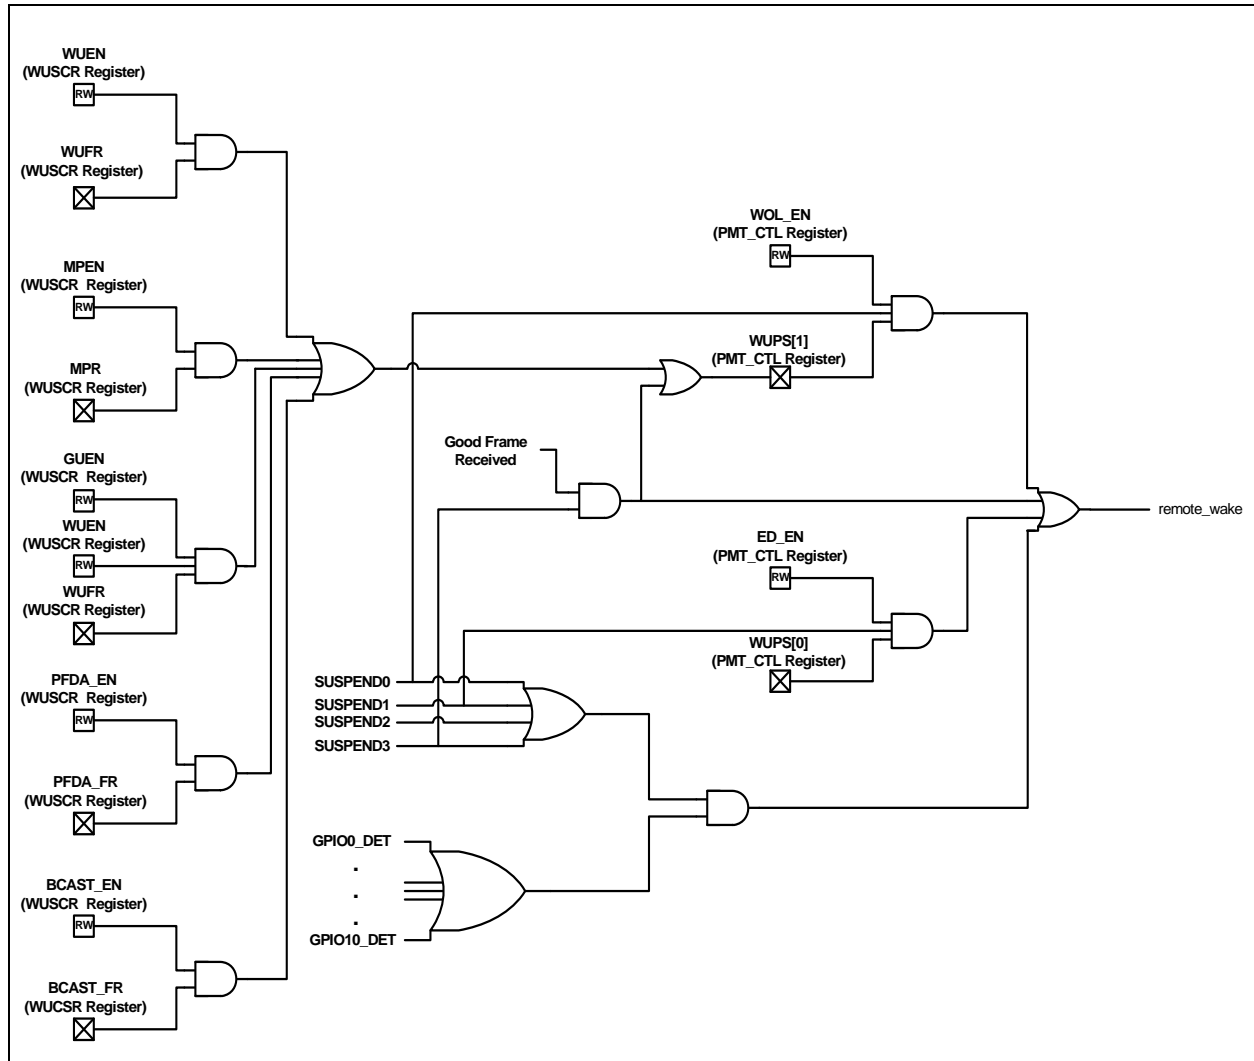

Note: The IME bit is in the [Hardware Configuration Register \(HW_CFG\)](#). [General Purpose IO Configuration Register \(GPIO_CFG\)](#) and [General Purpose IO Wake Enable and Polarity Register \(GPIO_WAKE\)](#) must be set accordingly. Diagram does not represent actual hardware implementation.

5.12.1.2 LAN9500A/LAN9500Ai Wake Detection Logic

A simplified diagram of the wake event detection logic for LAN9500A/LAN9500Ai is shown in [Figure 5-33](#).

FIGURE 5-33: WAKE EVENT DETECTION BLOCK DIAGRAM (LAN9500A/LAN9500AI)

Note: Diagram does not represent actual hardware implementation.

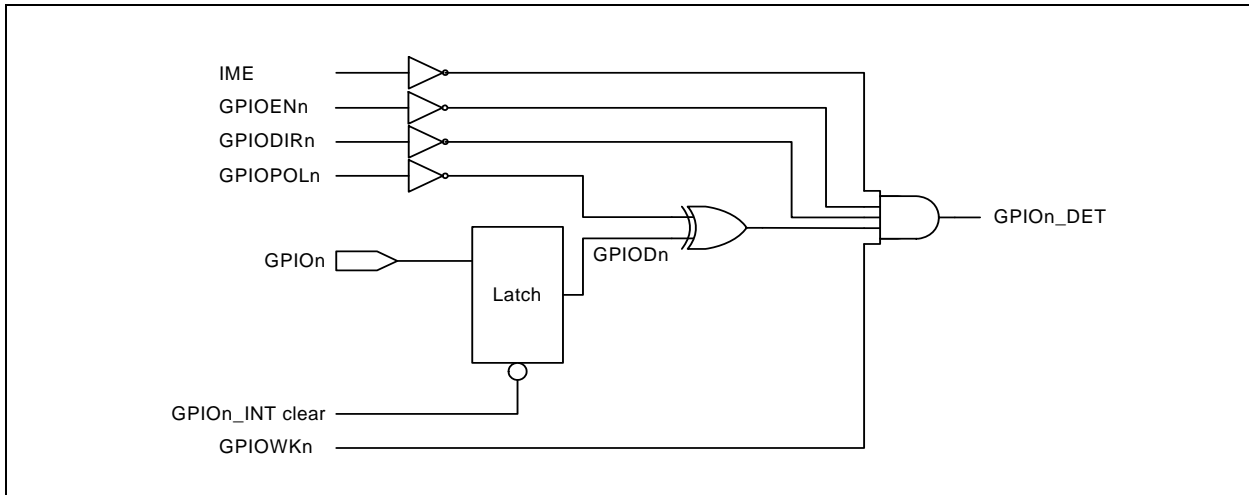

The functionality of GPIOs 0-6 and GPIOs 8-10 is slightly different. The functionality of GPIO7 is similar to that of GPIOs 0-6, with the additional requirement that it must cause a wakeup event when enabled for use in PHY Link Up detection.

Note: GPIOs 0-7 are only available for use during internal PHY Mode of operation. The functionality of GPIOs 0-6 is depicted in [Figure 5-34](#), while that of GPIO7 is shown in [Figure 5-35](#).

GPIOs 8-10 are available for use in both internal and external PHY mode of operation. Their functionality is depicted in [Figure 5-36](#).

LAN950x

Note: The IME bit is in the [Hardware Configuration Register \(HW_CFG\)](#). [General Purpose IO Configuration Register \(GPIO_CFG\)](#) and [General Purpose IO Wake Enable and Polarity Register \(GPIO_WAKE\)](#) must be set accordingly. Diagram does not represent actual hardware implementation.

FIGURE 5-35: DETAILED GPIO7 WAKE DETECTION LOGIC (LAN9500A/LAN9500AI)

Note: The IME bit is in the [Hardware Configuration Register \(HW_CFG\)](#). [General Purpose IO Configuration Register \(GPIO_CFG\)](#) and [General Purpose IO Wake Enable and Polarity Register \(GPIO_WAKE\)](#) must be set accordingly. [PHY Link Up Enable \(PHY_LINKUP_EN\)](#) bit of the [General Purpose IO Wake Enable and Polarity Register \(GPIO_WAKE\)](#) must be set if PHY Link Up is to cause wake event. Diagram does not represent actual hardware implementation.

FIGURE 5-36: DETAILED GPIOs 8-10 WAKE DETECTION LOGIC (LAN9500A/LAN9500Ai)

Note: The IME bit is in the [Hardware Configuration Register \(HW_CFG\)](#). [LED General Purpose IO Configuration Register \(LED_GPIO_CFG\)](#) and [General Purpose IO Wake Enable and Polarity Register \(GPIO_WAKE\)](#) must be set accordingly. Diagram does not represent actual hardware implementation.

5.12.1.3 Remote Wake Generation

5.12.1.3.1 Wake On LAN Event or Energy Detect

bit Control bits ([Note 5-6](#)) are implemented in the MAC's [WakeUp Control and Status Register \(WUCSR\)](#) to control Global Unicast Frame Wakeup, Magic Packet Wakeup, Wake Up Frame Detection Wakeup, Perfect DA Frame Wakeup, and Broadcast Frame Wakeup: GUEN, MPEN, WUEN, PFDA_EN, and BCAST_EN, respectively. A composite signal, depending on the state of these control bits and the associated event, is generated and propagated for further processing, as discussed in the following text.

Note 5-6 (LAN9500A/LAN9500Ai ONLY):
The five specified control bits are supported.

(LAN9500/LAN9500i ONLY):
Only three control bits are supported - GUEN, MPEN, WUEN.

Two control bits are implemented in the PMT_CTRL SCSR: Wake-on-LAN enable (WOL_EN) and Energy Detect enable (ED_EN). Depending on the state of these control bits, the logic will generate an internal wake event interrupt when the MAC detects a wakeup event (Global Unicast Frame, Wakeup Frame, Magic Packet, Perfect Destination Address Frame ([Note 5-7](#)), or Broadcast Frame ([Note 5-7](#)) - depending on the state of the aforementioned composite signal), or a PHY interrupt is asserted (energy detect). Two [WakeUp Status \(WUPS\)](#) bits are implemented in the SCSR space. These bits are set depending on the corresponding wake event. (See [Section 7.3.8, "Power Management Control Register \(PMT_CTL\)," on page 127](#) for further information). If a Wake-on-LAN event is detected, then further resolution on the source of the event can be obtained by examining the [Remote Wakeup Frame Received \(WUFR\)](#), [Magic Packet Received \(MPR\)](#), [Perfect DA Frame Received \(PFDA_FR\)](#) ([Note 5-7](#)), and [Broadcast Frame Received \(BCAST_FR\)](#) ([Note 5-7](#)) status bits in the MAC's [WakeUp Control and Status Register \(WUCSR\)](#).

LAN950x

Note 5-7 Supported only by **LAN9500A/LAN9500Ai**.

Note 1: Wake-on-LAN events resulting in the generation of a remote-wake event may only occur when in SUSPEND0 state.

2: Energy Detect events resulting in the generation of a remote-wake event may only occur when in SUSPEND1 state.

Wakeup Frame detection must be enabled in the MAC before detection can occur. Likewise, the energy detect interrupt must be enabled in the PHY before this interrupt can be used as a wake event. If the device is properly configured, the internal wake event interrupt will cause the assertion of the remote_wake signal on detection of a wake event.

5.12.1.3.2 Good Frame Detection (LAN9500A/LAN9500Ai ONLY)

To wakeup on reception of a frame passing the filtering constraints set solely by the [MAC Control Register \(MAC_CR\)](#), the enables for all Wake-On-LAN events contained in the [Wakeup Control and Status Register \(WUCSR\)](#) must be cleared and the desired constraints must be selected in MAC_CR. The setting of the [Wake-On-Lan Enable \(WOL_EN\)](#) bit of the [Power Management Control Register \(PMT_CTL\)](#) is a “don’t care”. The logic will generate an internal wake event interrupt when the MAC detects a frame passing the filtering constraints (“Good Frame”). The Wake-On-LAN bit of the [Wakeup Status \(WUPS\)](#) field of the [Power Management Control Register \(PMT_CTL\)](#) is used to signal wakeup due to reception of the “Good Frame”.

Note: “Good Frame” reception resulting in the generation of a remote-wake event may only occur when in the SUSPEND3 state.

5.12.1.3.3 GPIO Pin

GPIO pins 0 through 10 may cause the generation of a remote-wake event when properly configured and in any of the SUSPEND states. GPIO pins 0 through 7 each have a control bit (GPIOENx, 0<=x<=7) in the [General Purpose IO Configuration Register \(GPIO_CFG\)](#) that is used to enable the GPIO pin to generate a remote-wake event. GPIO pins 8 through 10 have no specific enable bit. The corresponding enable signal for these pins (GPIOENy, 8<=y<=10) is derived from the manner in which the pin is programmed. Ten GPIO wakeup status bits (GPIOWKy, 8<=y<=10) are available to determine the source of the event.

5.12.1.3.4 PHY Link Up (LAN9500A/LAN9500Ai ONLY)

GPIO7 may be programmed to signal a wakeup in SUSPEND0 or SUSPEND3 state on occurrence of a PHY Link Up. The [PHY Link Up Enable \(PHY_LINKUP_EN\)](#) bit of the [General Purpose IO Wake Enable and Polarity Register \(GPIO_WAKE\)](#) must be set to use GPIO7 for this purpose. When used in this mode, the signal connected to the device’s pin is ignored.

5.12.2 ENABLING WAKE EVENTS

5.12.2.1 Enabling GPIO Wake Events

The Host system must perform the following steps to enable the device to assert a remote_wake event on detection of a GPIO wake event.

1. The GPIO pin is programmed to facilitate generation of the wake event. If the pin is one of GPIO0 through GPIO7, the pin must be enabled to generate the event (GPIOENx must be clear in the [General Purpose IO Configuration Register \(GPIO_CFG\)](#)). If the pin is one of GPIO8 through GPIO10, the pin must be programmed as an input GPIO pin (the GPCTL and GPDIR fields for the pin in the [LED General Purpose IO Configuration Register \(LED_GPIO_CFG\)](#) must be set to 00b and 0, respectively). In addition, the pin must be enabled for wakeup and its desired polarity specified in the [GPIO Wake 0-10 \(GPIOWKn\)](#) and [GPIO Polarity 0-10 \(GPIOPOLn\)](#) fields, respectively, of the [General Purpose IO Wake Enable and Polarity Register \(GPIO_WAKE\)](#).
2. The Host places the device in the any one of the SUSPEND states by setting the [Suspend Mode \(SUSPEND_MODE\)](#) field of the [Power Management Control Register \(PMT_CTL\)](#) to indicate the desired suspend state, then sends suspend signaling.

On detection of an enabled GPIO wake event, the device will transition back to the NORMAL state and signal a remote_wake event. The Host may then examine the [GPIO \[10:0\] \(GPIOx_INT\)](#) status bits of the [Interrupt Status Register \(INT_STS\)](#) to determine the source of the wakeup.

5.12.2.2 Enabling WOL Wake Events

The Host system must perform the following steps to enable the device to assert a remote_wake event on detection of a Wake on LAN event.

1. All transmit and receive operations must be halted:
 - a) All pending Ethernet TX and RX operations must be completed.
 - b) The MAC must be halted.
2. The MAC must be configured to detect the desired wake event. This process is explained in [Section 5.5.5, "Wakeup Frame Detection,"](#) on page 59 for Wakeup Frames and in [Section 5.5.6, "Magic Packet Detection,"](#) on page 63 for Magic Packets.

(LAN9500A/LAN9500Ai ONLY):

Configuring Perfect DA and Broadcast Frame wakeup detection is analogous and requires the [Perfect DA Wakeup Enable \(PFDA_EN\)](#) or [Broadcast Wakeup Enable \(BCAST_EN\)](#) bit to be set in the [Wakeup Control and Status Register \(WUCSR\)](#).

3. Bit 1 of the Wakeup Status (WUPS[1]) in the [Power Management Control Register \(PMT_CTL\)](#) must be cleared since a set bit will cause the immediate assertion of wake event when the [Wake-On-Lan Enable \(WOL_EN\)](#) bit is set. The WUPS[1] bit will not clear if the internal MAC wakeup event is asserted.
4. Set the [Wake-On-Lan Enable \(WOL_EN\)](#) bit in the [Power Management Control Register \(PMT_CTL\)](#).
5. The Host places the device in the SUSPEND0 state by setting the [Suspend Mode \(SUSPEND_MODE\)](#) field in the [Power Management Control Register \(PMT_CTL\)](#) to 00b, to indicate the desired suspend state, then sends suspend signaling.

On detection of an enabled event, the device will transition back to the NORMAL state and signal a remote_wake event. The software will then examine the [Suspend Mode \(SUSPEND_MODE\)](#) field of the [Power Management Control Register \(PMT_CTL\)](#). Upon discovering wakeup occurred from SUSPEND0 state, the status bits of the WUCSR register may be examined to determine the particular event that caused the wakeup.

5.12.2.3 Enabling Link Status Change (Energy Detect) Wake Events

The Host system must perform the following steps to enable the device to assert a remote_wake event on detection of an Ethernet link status change.

1. All transmit and receive operations must be halted:
 - a) All pending Ethernet TX and RX operations must be completed.
 - b) The MAC must be halted.
2. The PHY must be enabled for the energy detect power down mode. This is done by clearing the [EDPWRDOWN](#) bit in the PHY's [Mode Control/Status Register](#). Enabling the energy detect power-down mode places the PHY in a reduced power state. In this mode of operation the PHY is not capable of receiving or transmitting Ethernet data. In this state, the PHY will assert its internal interrupt if it detects Ethernet activity. Refer to [Section 5.6.8.2, "Energy Detect Power-Down \(EDPD\),"](#) on page 78 for more information.
3. Bit 0 of the Wakeup Status (WUPS[0]) in the [Power Management Control Register \(PMT_CTL\)](#) must be cleared, since a set bit will cause the immediate assertion of wake event when [Energy-Detect Enable \(ED_EN\)](#) is set. The WUPS[0] bit will not clear if the internal PHY interrupt is asserted.
4. Set the [Energy-Detect Enable \(ED_EN\)](#) bit in the [Power Management Control Register \(PMT_CTL\)](#).
5. The Host places the device in the SUSPEND1 state by setting the [Suspend Mode \(SUSPEND_MODE\)](#) field in the [Power Management Control Register \(PMT_CTL\)](#) to 01b, to indicate the desired suspend state, then sends suspend signaling.

On detection of Ethernet activity (energy), the device will transition back to the NORMAL state and signal a remote_wake event.

LAN950x

5.12.2.4 Enabling PHY Link Up Wake Events (LAN9500A/LAN9500Ai ONLY)

The Host system must perform the following steps to enable the device to assert a remote_wake event on detection of PHY Link Up.

1. The system software determines that the link is down by periodically polling the [Link Status](#) bit of the [Basic Status Register](#).

Alternatively, the driver can detect assertion of the [PHY_INT](#) bit via the interrupt control endpoint. The driver may also detect PHY interrupt assertion by polling the [Interrupt Status Register \(INT_STS\)](#). It then reads the [Basic Status Register](#) and finds the [Link Status](#) bit is deasserted.

2. On finding the link down, the Host configures the device to wake up on PHY Link Up and signal the event using GPIO7 as follows:
 - a) The [PHY Link Up Enable \(PHY_LINKUP_EN\)](#) bit is set in the [General Purpose IO Wake Enable and Polarity Register \(GPIO_WAKE\)](#) to enable GPIO7 use in signaling the PHY Link Up event. The [GPIOWK7](#) bit is also set in the register to permit its use in wake event generation. The setting of [GPIOPOL7](#) is a “don’t care”.
 - b) The following additional parameters for GPIO7 must be configured in the [General Purpose IO Configuration Register \(GPIO_CFG\)](#) : [GPIOEN7](#) = 0, [GPIODIR7](#) = 0, [GPIOBUF7](#) = “don’t care”.
3. The [GPIO7_INT](#) bit in the [Interrupt Status Register \(INT_STS\)](#) must be cleared, since a set bit will cause the immediate assertion of the wake event.
4. The Host places the device in the [SUSPEND0](#) or [SUSPEND3](#) state, as appropriate, by setting the [Suspend Mode \(SUSPEND_MODE\)](#) field in the [Power Management Control Register \(PMT_CTL\)](#) to 00b or 11b, to indicate the desired suspend state. The Host then sends suspend signaling.

On detection of PHY Link Up, the device will transition back to the [NORMAL](#) state and signal a remote_wake event. The Host, in trying to determine the cause of the wake event, may then examine the [GPIO \[10:0\] \(GPIOx_INT\)](#) status bits of the [Interrupt Status Register \(INT_STS\)](#). On finding [GPIO7_INT](#) set, the software will then use the [Suspend Mode \(SUSPEND_MODE\)](#) field of the [Power Management Control Register \(PMT_CTL\)](#) and the value of the [PHY Link Up Enable \(PHY_LINKUP_EN\)](#) bit to determine a PHY Link Up wake event occurred.

5.12.2.5 Enabling “Good Frame” Wake Events (LAN9500A/LAN9500Ai ONLY)

The Host system must perform the following steps to enable the device to assert a remote_wake event on detection of a “Good Frame”.

1. The MAC filtering is configured by setting the desired constraints in the [MAC Control Register \(MAC_CR\)](#). All Wake-On-LAN events contained in the [Wakeup Control and Status Register \(WUCSR\)](#) must be disabled. The setting of the [Wake-On-Lan Enable \(WOL_EN\)](#) bit of the [Power Management Control Register \(PMT_CTL\)](#) is a “don’t care”.
2. Bit 1 of the Wakeup Status ([WUPS\[1\]](#)) in the [Power Management Control Register \(PMT_CTL\)](#) must be cleared since a set bit will cause the immediate assertion of wake event. The [WUPS\[1\]](#) bit will not clear if the internal MAC wakeup event is asserted.
3. The Host places the device in the [SUSPEND3](#) state by setting the [Suspend Mode \(SUSPEND_MODE\)](#) field in the [Power Management Control Register \(PMT_CTL\)](#) to 11b, to indicate the desired suspend state, then sends suspend signaling.

On detection of a “Good Frame”, the device will transition back to the [NORMAL](#) state and signal a remote_wake event. The software will then examine the [Suspend Mode \(SUSPEND_MODE\)](#) field of the [Power Management Control Register \(PMT_CTL\)](#). Upon discovering wakeup occurred from [SUSPEND3](#) state, the host may perform desired processing as a result of receiving the “Good Frame”.

5.12.3 NETDETACH (LAN9500A/LAN9500AI ONLY)

NetDetach is a mode of operation where the device detaches from the USB bus after the Ethernet cable is disconnected. This is advantageous for mobile devices, as an attached USB device prevents the Host CPU from entering the [APCI C3](#) state. Allowing the CPU to enter the [C3](#) state maximizes battery life.

When detached, the device’s power state is essentially the same as the [SUSPEND1](#) state. After the Ethernet cable is reconnected, or a programmed GPIO pin asserts, the device automatically attaches to the USB bus. GPIO pin assertion is supported so that this feature can be used with external PHY mode. In this case, the external PHY’s link LED would be connected to a GPIO.

The NetDetach feature requires assistance of the driver. The driver will monitor the link status of the Ethernet PHY and program the device appropriately to detach and re-attach to the USB bus upon link up. The following steps illustrate this process:

1. User disconnects the Ethernet cable.
2. Driver detects assertion of the [PHY_INT](#) bit via the interrupt control endpoint. The driver may also detect PHY interrupt assertion by polling the [Interrupt Status Register \(INT_STS\)](#).
3. Driver reads the [Basic Status Register](#) and finds the [Link Status](#) bit is deasserted.
4. At this point, the Driver may place the Ethernet PHY into either the Energy Detect Power-Down mode or the PHY Link Up Detection mode. [Section 5.12.2.3, "Enabling Link Status Change \(Energy Detect\) Wake Events," on page 107](#) and [Section 5.12.2.4, "Enabling PHY Link Up Wake Events \(LAN9500A/LAN9500Ai ONLY\)," on page 108](#) provide detailed instructions for programming these modes.
5. Driver sets the [NetDetach Enable \(SMDET_EN\)](#) bit in the [Hardware Configuration Register \(HW_CFG\)](#).
6. The device then detaches from the USB bus and disables the USB PLL. The driver is unloaded at this point and can no longer communicate with the device.
7. At some point in the future, the Ethernet cable is reconnected, or an appropriately configured GPIO pin is asserted.
8. The device attaches to the USB bus.
9. The driver is loaded and the device is configured by the driver. The driver examines the [NetDetach Status \(SMDET_STS\)](#) bit in the [Hardware Configuration Register \(HW_CFG\)](#) to determine if it was reloaded as a result of coming back from a NetDetach operation or for some other reason.

5.13 Resets

The device has the following chip level reset sources:

- [Power-On Reset \(POR\)](#)
- [External Chip Reset \(nRESET\)](#)
- [Lite Reset \(LRST\)](#)
- [Soft Reset \(SRST\)](#)
- [USB Reset](#)
- [PHY Software Reset](#)
- [nTRST](#)
- [VBUS_DET](#)

5.13.1 POWER-ON RESET (POR)

A Power-On reset occurs whenever power is initially applied to the device, or if power is removed and reapplied to the device. A timer within the device will assert the internal reset for approximately 22mS.

Note 1: The EEPROM contents are loaded by this reset.

- 2: After the assertion of the POR, the internal Ethernet PHY is put into general power down mode.

5.13.2 EXTERNAL CHIP RESET (NRESET)

A hardware reset will occur when the nRESET pin is driven low. The READY bit in the PMT_CTRL register can be read by the Host, and will read back a '0' until the hardware reset is complete. Upon completion of the hardware reset, the READY bit in PMT_CTRL is set high.

After the "READY" bit is set, the device can be configured via its control registers. The nRESET pin is pulled-high internally by the device and can be left unconnected if unused. If used, nRESET must be driven low for a minimum period as defined in [Section 8.5.3, "Reset and Configuration Strap Timing," on page 197](#). If nRESET is unused, the device must be reset following power-up via a soft reset (SRST).

Note 1: After the assertion of nRESET, the internal Ethernet PHY is put into general power down mode.

- 2: nRESET is ignored when the device is in the UNPOWERED state. As in the UNPOWERED state the entire chip is held in reset.

5.13.3 LITE RESET (LRST)

This reset is initiated via the LRST bit in the [Section 7.3.5, "Hardware Configuration Register \(HW_CFG\)"](#). It will reset the entire chip with the exception of the USB Device Controller and the USB PHY (UDC, parts of the CTL, and the USB PHY). The PLL is not turned off.

- Note 1:** This reset does not cause the USB contents from the EEPROM to be reloaded.
- 2:** This reset does not place the device into the Unconfigured state.
- 3:** After the LRST, the USB pipes corresponding to the Bulk In, Bulk Out, and Interrupt endpoints must be reset. This process entails clearing the device's ENDPOINT_HALT feature and resetting the data toggle on the host side.

5.13.4 SOFT RESET (SRST)

A Soft reset is initiated by writing a '1' to bit 0 of the HW_CFG register (SRST). This self-clearing bit will return to '0' after approximately 2 μ s, at which time the Soft Reset is complete. Soft reset does not clear control register bits marked as NASR.

- Note 1:** The EEPROM contents are reloaded by this reset.
- 2:** After the assertion of the SRST the internal Ethernet PHY is put into general power down mode.

Writing SRST=1 will cause the device to disconnect from the USB shortly after the first good OUT Data pkt during the Data Phase. In HS mode, a brief delay will allow enough time for the device to send the ACK for the Data Stage, but the device will be disconnected (causing a 3-strikes timeout failure) for any next transaction (e.g., the Status Stage, or a repeated Data Stage, if there were any bus errors). In FS mode, the brief delay will be short enough that the device will disconnect during the ACK pkt, causing CRC, bit-stuff, etc. errors on USB. To the USB Host, the aforementioned behaviors are the same as what happens during any Surprise Removal of a USB Device. This behavior is completely normal, and a compliant Host must be tolerant of it.

5.13.5 USB RESET

A USB reset causes a reset of the entire chip with the exception of the USB Device Controller and the USB PHY (UDC, parts of the CTL, and the USB PHY). The PLL is not turned off. It will occur after a POR, nRESET, or SRST (These will all force disconnects of the USB bus). After a USB reset, the READY bit in the PMT_CTRL register can be read by the Host and will read back a '0' until the EEPROM contents are loaded (provided one is present). Upon completion of the EEPROM contents load, the READY bit in PMT_CTRL is set high, and the device can be configured via its control registers.

- Note 1:** This reset does not cause the USB contents from the EEPROM to be reloaded. Only the MAC address is reloaded.
- 2:** After the assertion of the USB Reset the internal Ethernet PHY is put into general power down mode.

5.13.6 PHY SOFTWARE RESET

The Ethernet PHY can be reset via two software-initiated resets. Please refer to [Section 5.6.9, "PHY Resets," on page 78](#) for details.

5.13.7 NTRST

This active-low reset is used by the TAP controller.

5.13.8 VBUS_DET

The removal of USB power causes the device to transition to the UNPOWERED state. The chip is held in reset while in the UNPOWERED state.

- Note 1:** After VBUS_DET is asserted, the contents of the EEPROM are reloaded.
- 2:** After transitioning out of the UNPOWERED state, the internal Ethernet PHY is in general power down mode.

5.14 Configuration Straps

Configuration straps are multi-function pins that are driven as outputs during normal operation. During a [Power-On Reset \(POR\)](#) or a [External Chip Reset \(nRESET\)](#), these outputs are tri-stated. The high or low state of the signal is latched following de-assertion of the reset and is used to determine the default configuration of a particular feature. Configuration strap signals are noted in [Section 3.0, "Pin Description and Configuration," on page 11](#).

Configuration straps are latched as a result of a [Power-On Reset \(POR\)](#) or a [External Chip Reset \(nRESET\)](#).

bit Configuration straps include internal resistors in order to prevent the signal from floating when unconnected. If a particular configuration strap is connected to a load, an external pull-up or pull-down should be used to augment the internal resistor to ensure that it reaches the required voltage level prior to latching. The internal resistor can also be overridden by the addition of an external resistor.

Note 1: The system designer must ensure that configuration straps meet the timing requirements specified in [Section 8.5.3, "Reset and Configuration Strap Timing," on page 197](#) and [Section 8.5.2, "Power-On Configuration Strap Valid Timing," on page 196](#). If configuration straps are not at the correct voltage level prior to being latched, the device may capture incorrect strap values.

- 2:** Configuration straps must never be driven as inputs. If required, configuration straps can be augmented, or overridden with external resistors.

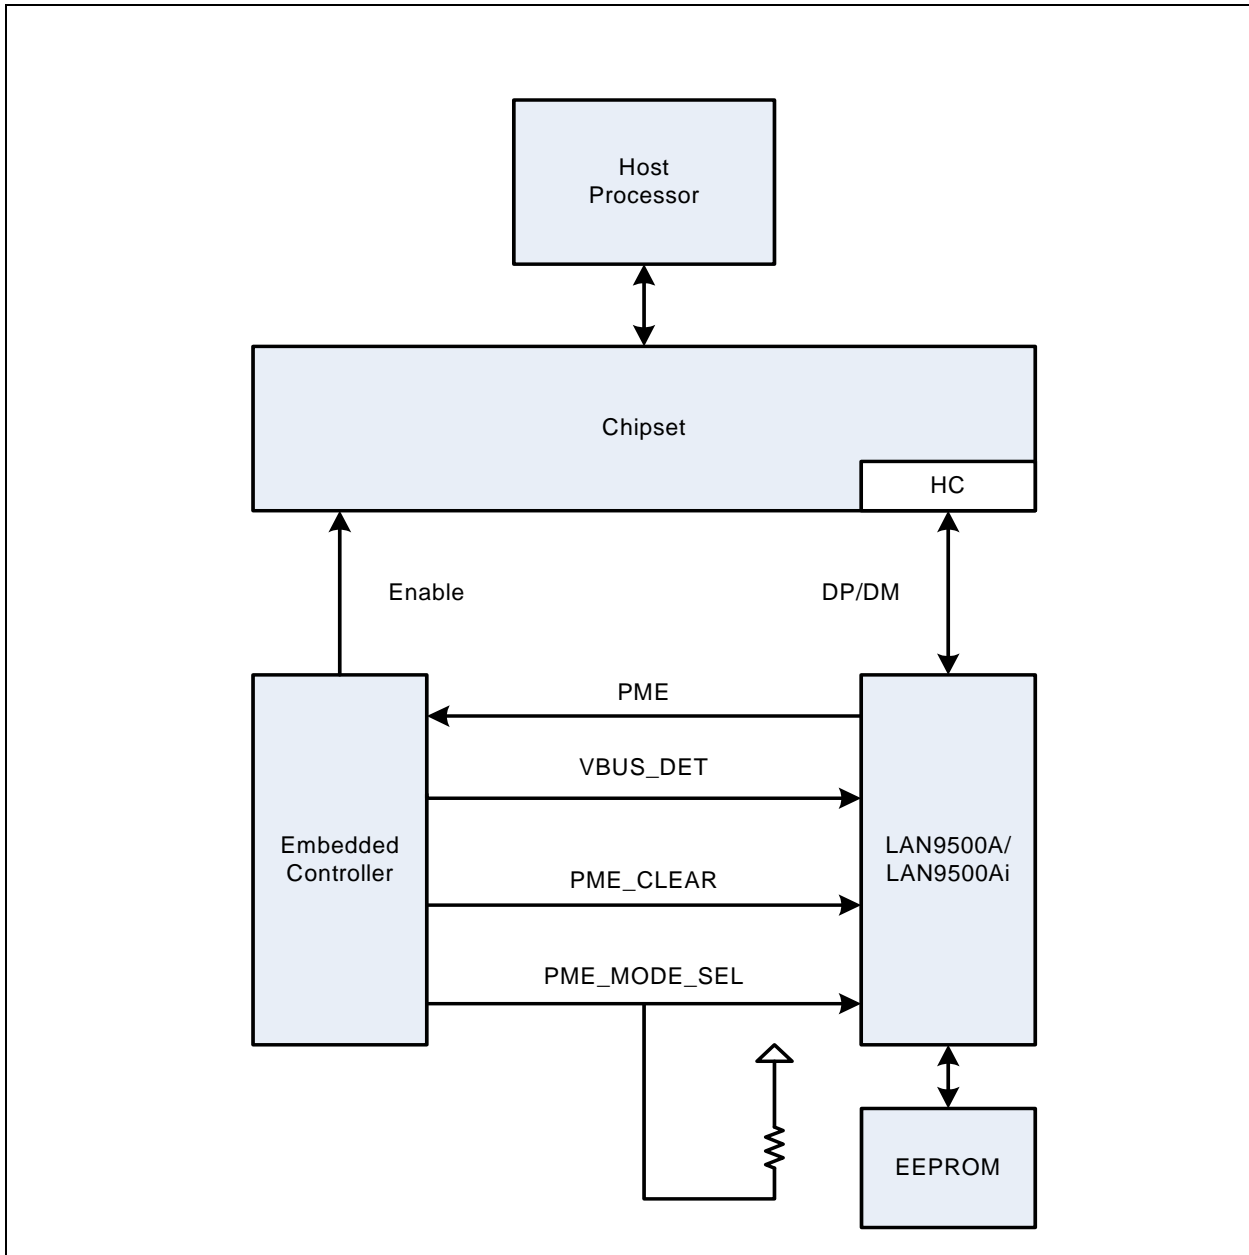

LAN950x

6.0 PME OPERATION

PME Operation is supported only by LAN9500A/LAN9500Ai.

The device provides a mechanism for waking up a host system via PME mode of operation. PME signaling is only available while the device is operating in the self powered mode. [Figure 6-1](#) illustrates a typical application using LAN9500A/LAN9500Ai.

FIGURE 6-1: TYPICAL APPLICATION

The Host Processor is connected to a Chipset containing the Host USB Controller (HC). The USB Host Controller interfaces to the device via the DP/DM USB signals. An Embedded Controller (EC) signals the Chipset and the Host processor to power up via an Enable signal. The EC interfaces to the device via four signals. The PME signal is an input to the EC from the device that indicates the occurrence of a wakeup event. The VBUS_DET output of the EC is used to indicate bus power availability. The PME_CLEAR (nRESET) signal is used to clear the PME. The PME_MODE_SEL signal is sampled by the device when PME_CLEAR (nRESET) is asserted and is used by the device to determine whether it should remain in PME mode or resume normal operation.

GPIO pins are used for PME handling. The pins used depend on the value of the [PHY_SEL](#) pin, which determines PHY mode of operation. In Internal PHY mode of operation, GPIO0 is reserved for use as an output to signal the PME. GPIO1 is reserved for use as the PME_MODE_SEL input. GPIO8 and GPIO9 are reserved for analogous use, respectively, in External PHY mode of operation.

The application scenario in [Figure 6-1](#) assumes that the Host Processor and the Chipset are powered off, the EC is operational, and the device is in PME mode, waiting for a wake event to occur. A wake event will result in the device signaling a PME event to the EC, which will then wake up the Host Processor and Chipset via the Enable signal. The EC asserts VBUS_DET after the USB bus is powered, sets PME_MODE_SEL to determine whether the device is to begin normal operation or continue in PME mode, and asserts PME_CLEAR (nRESET) to clear the PME.

The following wake events are supported:

- Wakeup Pin(s)
The GPIO pins not reserved for PME handling have the capability to wake up the device when operating in PME mode. In order for a GPIO to generate a wake event, it must be configured as an input. GPIOs used as wake events must also be enabled by the GPIO_WAKE register, see [Section 7.3.20, "General Purpose IO Wake Enable and Polarity Register \(GPIO_WAKE\)"](#). On POR or nRESET, all GPIOs default to inputs and the default value of the [GPIO Wake 0-10 \(GPIOWKn\)](#) field of the GPIO_WAKE register is set from the contents of the EEPROM. During PME mode of operation, the GPIOs used for signaling (GPIOs 0 and 1 or GPIOs 8 and 9) are not affected by the register defaults.

GPIO10 is available as a wakeup pin in External PHY mode, while GPIOs 2 - 10 are available in Internal PHY Mode. The [GPIO10 Detection Select](#) bit in the [GPIO PME Flags](#) byte of the EEPROM sets the detection mode for GPIO10 in both External and Internal PHY mode (if enabled via the GPIO_WAKE register), while GPIOs 2 - 9 are active low (by default) when operating in Internal PHY mode.

- Magic Packet
Reception of a Magic Packet when in PME mode will result in a PME being asserted.
- PHY Link Up
Detection of a PHY link partner when in PME mode will result in a PME being asserted.

In order to facilitate PME mode of operation, the [GPIO PME Enable](#) bit in the [GPIO PME Flags](#) field, must be set and all remaining [GPIO PME Flags](#) field bits must be appropriately configured for pulse or level signaling, buffer type, and GPIO PME WOL selection. The PME event is signaled on GPIO0 (External PHY mode) or GPIO8, depending on the PHY Mode of operation.

The PME_MODE_SEL pin (GPIO1 in Internal Mode of operation, GPIO9 in External Mode of operation) must be driven to the value that determines whether or not the device remains in PME mode of operation (1) or resumes normal operation (0) when the PME is recognized and cleared by the EC via PME_CLEAR (nRESET) assertion.

Note 1: The device's software driver is unaware of PME mode. No internal mechanism exists for the driver to examine the internal hardware to determine the setting of the [GPIO PME Flags](#) read from the EEPROM on POR or nRESET. PME mode is not visible via the GPIO registers or via the INT_STS register. I.e., if a GPIO pin or reception of a Magic Packet results in a PME, the INT_STS register is not updated to indicate the occurrence of the event. The driver has no mechanism available to clear the PME. The driver can not program any GPIO register associated with the PME until the EC asserts nRESET to clear PME mode.

- 2: When in PME mode, nRESET or POR will always cause the contents of the EEPROM to be reloaded.
- 3: GPIO10 may be used in PME and External PHY mode to connect to an external PHY's Link LED, in order to generate a PHY Link Up wake event.

LAN950x

Figure 6-2 flowcharts PME operation while in Internal PHY mode. The following conditions hold:

EEPROM Configuration:

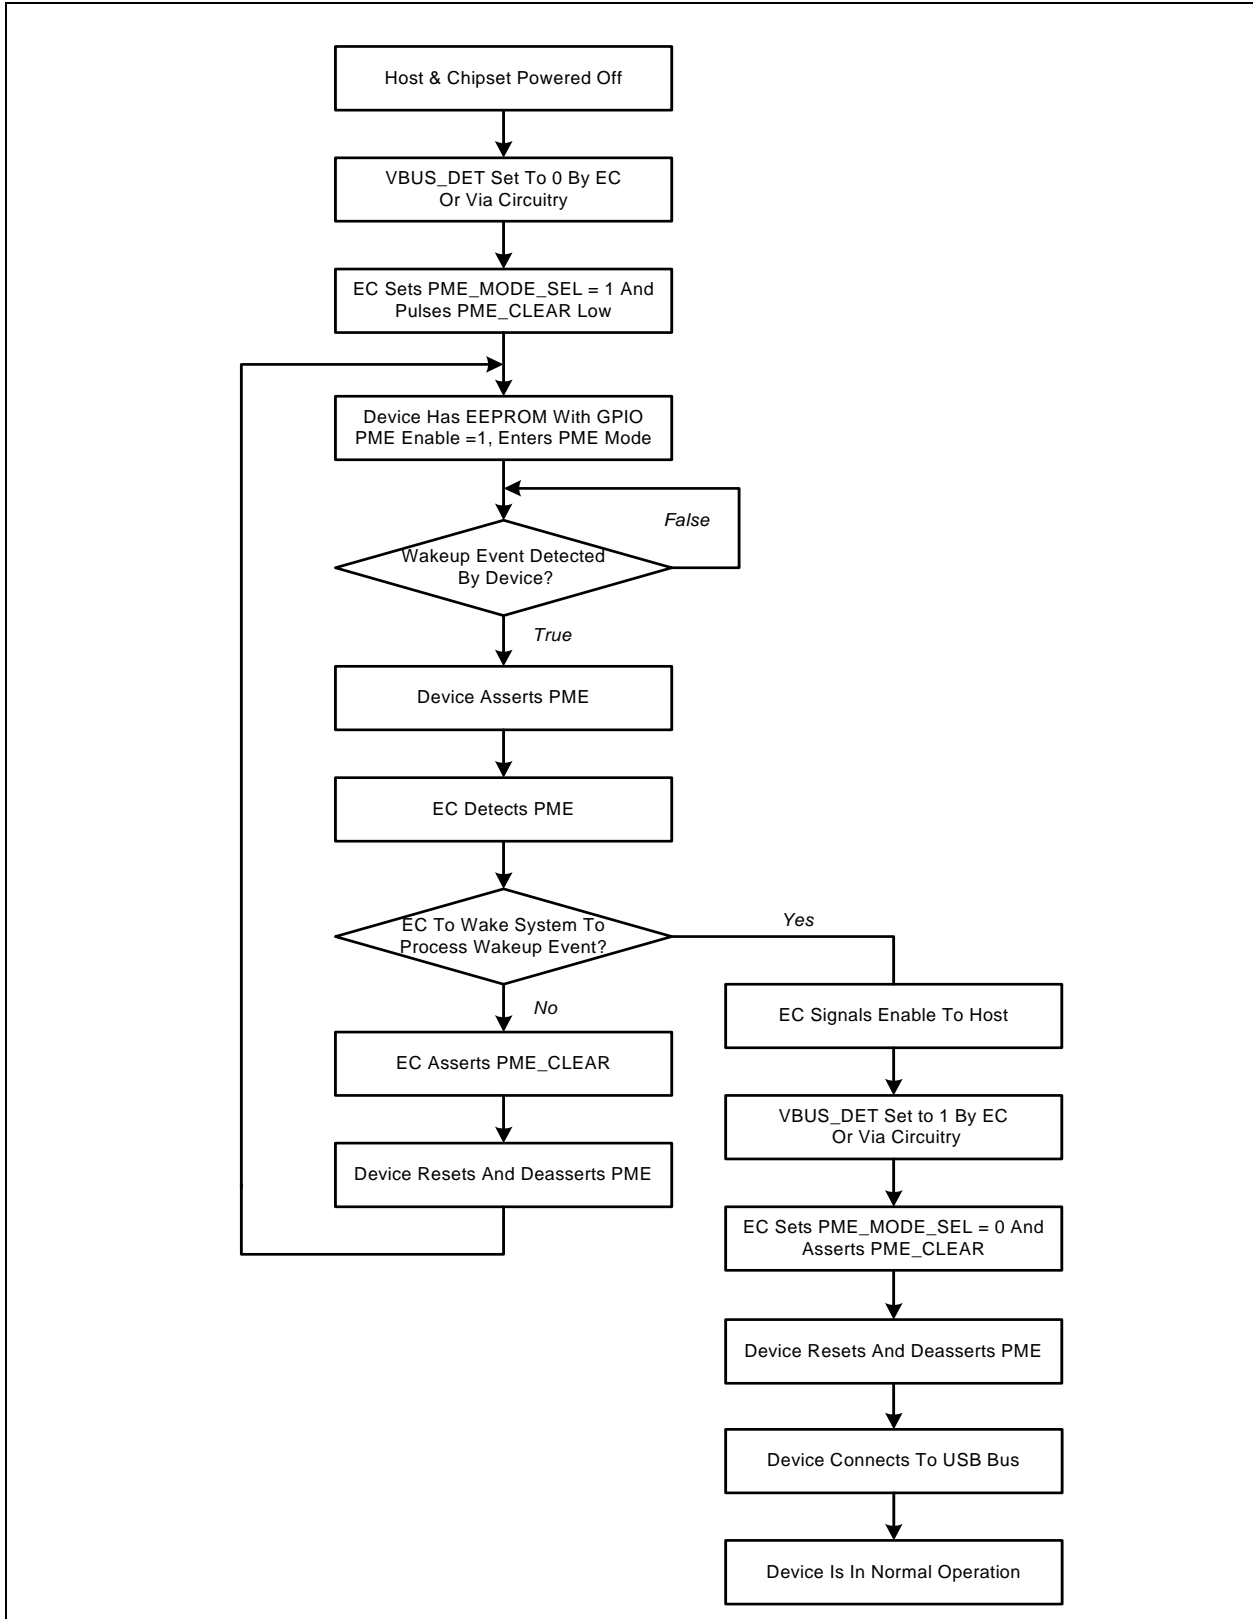

- GPIO PME Enable = 1 (enabled)
- GPIO PME Configuration = 0 (PME signaled via level on GPIO pin)
- GPIO PME Length = 0 (NA)
- GPIO PME Polarity = 1 (high level signals event)
- GPIO PME Buffer Type = 1 (Push-Pull)
- GPIO PME WOL Select = 0 (Magic Packet wakeup)
- GPIO10 Detection Select = 0 (Active-low detection)
- Power Method = 1 (self powered)
- MAC address for Magic Packet

PME signaling configuration (as determined by PHY Mode)

- GPIO0 signals PME
- GPIO1 is PME_MODE_SEL

| |
|--|
| Note: A POR occurring when PME_MODE_SEL = 1 and an EEPROM present with the GPIO PME Enable set results in the device entering PME Mode. |
|--|

FIGURE 6-2: PME OPERATION

7.0 REGISTER DESCRIPTIONS

7.1 Register Nomenclature

Table 7-1 describes the register bit attributes used throughout this document.

TABLE 7-1: REGISTER BIT TYPES

| Register Bit Type Notation | Register Bit Description |
|----------------------------|--|
| R | Read: A register or bit with this attribute can be read. |
| W | Write: A register or bit with this attribute can be written. |
| RO | Read only: Read only. Writes have no effect. |
| RS | Read to Set: This bit is set on read. |
| WO | Write only: If a register or bit is write-only, reads will return unspecified data. |
| WC | Write One to Clear: writing a one clears the value. Writing a zero has no effect. |
| WAC | Write Anything to Clear: writing anything clears the value. |
| RC | Read to Clear: Contents is cleared after the read. Writes have no effect. |
| LL | Latch Low: Clear on read of register. |
| LH | Latch High: Clear on read of register. |
| SC | Self-Clearing: Contents is self-cleared after the being set. Writes of zero have no effect. Contents can be read. |
| RO/LH | Read Only, Latch High: This mode is used by the Ethernet PHY registers. Bits with this attribute will stay high until the bit is read. After it a read, the bit will remain high, but will change to low if the condition that caused the bit to go high is removed. If the bit has not been read the bit will remain high regardless of if its cause has been removed. |
| NASR | Not Affected by Software Reset. The state of NASR bits does not change on assertion of a software reset. |
| RESERVED | Reserved Field: Reserved fields must be written with zeros, unless otherwise indicated, to ensure future compatibility. The value of reserved bits is not guaranteed on a read. |

7.2 Register Memory Map

TABLE 7-2: LAN950X REGISTER MEMORY MAP

| Address | Symbol | Register Name |
|-------------|--------|-------------------------------------|
| 000h - 0FFh | SCSR | System Control and Status Registers |
| 100h - 1FCh | MCSR | MAC Control and Status Registers |

7.3 System Control and Status Registers

TABLE 7-3: LAN950X DEVICE CONTROL AND STATUS REGISTER MAP

| Address | Symbol | Register Name |
|-------------------------------|-----------------|--|
| 000h | ID_REV | Device ID and Revision Register |

| 0B0h Note 7-1 | FLAG_ATTR | Flag Attributes Register |
| 0B4h – 0FFh | RESERVED | Reserved for future expansion |

Note 7-1 Featured in LAN9500A/LAN9500Ai to support custom operation without EEPROM. RESERVED in LAN9500/LAN9500i.

LAN950x

7.3.1 DEVICE ID AND REVISION REGISTER (ID_REV)

Address: 000h Size: 32 bits

| Bits | Description | Type | Default |
|-------|---|------|--------------------------|
| 31:16 | Chip ID This read-only field identifies the device model. | RO | Note 7-2 |
| 15:0 | Chip Revision This is the revision of the device. | RO | Note 7-3 |

Note 7-2 Device models are:

| Product | ID |
|--------------------|-------|
| LAN9500/LAN9500i | 9500h |
| LAN9500A/LAN9500Ai | 9E00h |

Note 7-3 Default value is dependent on device revision.

7.3.2 INTERRUPT STATUS REGISTER (INT_STS)

Address: 008h Size: 32 bits

| Bits | Description | Type | Default |
|-------|---|----------------------------------|--------------------------|
| 31:19 | RESERVED | RO | - |
| 18 | MAC Reset Time Out (MACRTO_INT) This interrupt signifies that the 8 ms reset watchdog timer has timed out. This means that the Ethernet PHY is not supplying the rx_clk or tx_clk. After the timer times out, the MAC reset is deasserted asynchronously. | R/WC | 0b |
| 17 | TX Stopped (TXSTOP_INT) This interrupt is asserted when the Stop Transmitter (STOP_TX) bit in Transmit Configuration Register (TX_CFG) is set and the transmitter is halted. Note: The source of this interrupt is a pulse. | R/WC | 0b |
| 16 | RX Stopped (RXSTOP_INT) This interrupt is issued when the receiver is halted. Note: The source of this interrupt is a pulse. | R/WC | 0b |
| 15 | PHY Interrupt (PHY_INT) Indicates a PHY Interrupt event. Note 1: Depending on configuration, this may report the interrupt status of the internal or the external PHY. 2: The source of this interrupt is a level. The interrupt persists until it is cleared in the PHY. | RO | - |
| 14 | Transmitter Error (TXE) When generated, indicates that the transmitter has encountered an error. Refer to Section 5.4.2.5, "TX Error Detection" for a description of the conditions that will cause a TXE. Note: The source of this interrupt is a pulse. | R/WC | 0b |
| 13 | TX Data FIFO Underrun Interrupt (TDFU) Generated when the TX Data FIFO underruns. Note: The source of this interrupt is a pulse. | R/WC | 0b |
| 12 | TX Data FIFO Overrun Interrupt (TDFO) Generated when the TX Data FIFO is full, and another write is attempted. Note 1: This interrupt should never occur and indicates a catastrophic hardware error. 2: The source of this interrupt is a pulse. | R/WC | 0b |
| 11 | RX Dropped Frame Interrupt (RXDF_INT) This interrupt is issued whenever a receive frame is dropped. Note: The source of this interrupt is a pulse. | R/WC | 0b |
| 10:0 | GPIO [10:0] (GPIOx_INT) Interrupts are generated from the GPIOs. These interrupts are configured through the GPIO_CFG and LED_GPIO_CFG registers. Note: The sources for these interrupts are a level. | R/WC Note 7-5 | Note 7-4 |

Note 7-4 The default depends on the state of the GPIO pin.

Note 7-5 The clearing of a GPIOx_INT bit also clears the corresponding GPIO wake event.

LAN950x

7.3.3 RECEIVE CONFIGURATION REGISTER (RX_CFG)

Address: 00Ch Size: 32 bits

| Bits | Description | Type | Default |
|------|--|------|---------|
| 31:1 | RESERVED | RO | - |
| 0 | Receive FIFO Flush Setting this bit will reset the RX FIFO pointers. | SC | 0b |

7.3.4 TRANSMIT CONFIGURATION REGISTER (TX_CFG)

Address: 010h Size: 32 bits

| Bits | Description | Type | Default |
|------|---|------|---------|
| 31:3 | RESERVED | RO | - |
| 2 | Transmitter Enable (TX_ON) When this bit is set, the transmitter is enabled. Any data in the TX FIFO will be sent. This bit is cleared automatically when STOP_TX is set and the transmitter is halted. | R/W | 0b |
| 1 | Stop Transmitter (STOP_TX) When this bit is set, the transmitter will finish the current frame being read from the TX FIFO, and will then stop transmitting. When the transmitter has stopped, this bit will clear. All writes to this bit are ignored while this bit is high. Note: After this bit clears, there will be no TX Ethernet frame data in the TX datapath. | SC | 0b |
| 0 | Transmit FIFO Flush Setting this bit will reset the TX FIFO pointers. | SC | 0b |

LAN950x

7.3.5 HARDWARE CONFIGURATION REGISTER (HW_CFG)

Address: 014h Size: 32 bits

| Bits | Description | Type | Default |
|-------|---|------|--------------------------|
| 31:19 | RESERVED | RO | - |
| 18 | (LAN9500A/LAN9500Ai ONLY, Otherwise RESERVED) NetDetach Status (SMDET_STS) After the driver loads, this bit is checked to determine whether an NetDetach event occurred. | R/WC | Note 7-6 |
| 17 | (LAN9500A/LAN9500Ai ONLY, Otherwise RESERVED) NetDetach Enable (SMDET_EN) When this bit is set, the device detaches from the USB bus. This results in the driver unloading and no further communication with the device. The device remains detached until PHY link is detected, or a properly configured GPIO pin is asserted. Occurrence of either event causes the device to attach to the USB bus, the driver to be loaded, and the SMDET_STS bit to be asserted. | SC | 0b |
| 16 | (LAN9500A/LAN9500Ai ONLY, Otherwise RESERVED) EEPROM Emulation Enable (EEM) This bit is used to select the source of descriptor information and configuration flags when no EEPROM is present. 0 = Use defaults as specified in Section 5.7.2, "EEPROM Defaults," on page 82. 1 = Use Descriptor RAM and Attributes Registers Note 1: This bit affects operation only when a EEPROM is not present. This bit has no effect when a EEPROM is present. 2: This field is protected by Reset Protection (RST_PROTECT) . | R/W | 0b |
| 15 | (LAN9500A/LAN9500Ai ONLY, Otherwise RESERVED) Reset Protection (RST_PROTECT) Setting this bit protects select fields of certain registers from being affected by resets other than POR. Note: This field is protected by Reset Protection (RST_PROTECT) . | R/W | 0b |
| 14:13 | (LAN9500A/LAN9500Ai ONLY, Otherwise RESERVED) PHY Boost (PHY_BOOST) This field provides the ability to boost the electrical drive strength of the HS output current to the upstream port. 00 = Normal electrical drive strength 01 = Elevated electrical drive strength (+4% boost) 10 = Elevated electrical drive strength (+8% boost) 11 = Elevated electrical drive strength (+12% boost) Note: This field is protected by Reset Protection (RST_PROTECT) . | R/W | Note 7-7 |
| 12 | Bulk In Empty Response (BIR) This bit controls the response to Bulk IN tokens when the RX FIFO is empty. 0 = Respond to the IN token with a ZLP 1 = Respond to the IN token with a NAK | R/W | 0b |
| 11 | Activity LED 80 ms Bypass (LEDB) When set, the Activity LED on/off time is reduced to approximately 15us/15us. | R/W | 0b |

| Bits | Description | Type | Default |
|------|--|------|--------------------------|
| 10:9 | <p>RX Data Offset (RXDOFF) This field controls the amount of offset, in bytes, that is added to the beginning of an RX Data packet. The start of the valid data will be shifted by the amount of bytes specified in this field. An offset of 0-3 bytes is a valid number of offset bytes.</p> <p>Note: This register may not be modified after the RX datapath has been enabled.</p> | R/W | 00b |
| 8 | <p>Stall Bulk Out Pipe Disable (SBP) This bit controls the operation of the Bulk Out pipe when the FCT detects the loss of sync condition. Please refer to Section 5.4.2.5, "TX Error Detection" for details.</p> <p>0 = Stall the Bulk Out pipe when loss of sync detected. 1 = Do not stall the Bulk Out pipe when loss of sync detected.</p> | R/W | 0b |
| 7 | <p>Internal MII Visibility Enable (IME) This register enables a subset of the MII interface to be visible on unused pins when configured for the internal Ethernet PHY mode. The pins controlled by the IME bit are comprised of the pins listed in Table 3-1, "MII Interface Pins," on page 12 and the nPHY_INT pin.</p> <p>0 = The MII signals are not visible. The MII pins function as inputs. 1 = The MII signals are visible. The MII pins function as outputs.</p> <p>Note 1: This register has no affect when using an external PHY. 2: The IME has priority over the GPIO_CFG register. When IME is asserted, the pins CRS, MDC, MDIO, COL, TXD3, TXD2, TXD1, and TXD0 can not be configured for GPIO operation.</p> | RW | 0b |
| 6 | <p>Discard Errored Received Ethernet Frame (DRP) This bit will cause errored Ethernet frames to be discarded when enabled.</p> <p>0 = Do not discard errored Ethernet frames 1 = Discard errored Ethernet frames.</p> | R/W | 0b |
| 5 | <p>Multiple Ethernet Frames per USB Packet (MEF) This bit enables the USB transmit direction to pack multiple Ethernet frames per USB packet whenever possible.</p> <p>0 = Support no more than one Ethernet frame per USB packet 1 = Support packing multiple Ethernet frames per USB packet</p> <p>Note: The URX supports this mode by default.</p> | R/W | 0b |
| 4 | <p>EEPROM Time-out Control (ETC) This bit controls the length of time used by the EEPROM controller to detect a time-out.</p> <p>0 = Time-out occurs if no response received from EEPROM after 30 ms. 1 = Time-out occurs if no response received from EEPROM after 1.28 us.</p> | R/W | 0b |
| 3 | <p>Soft Lite Reset (LRST) Writing 1 generates the lite software reset of the device.</p> <p>A lite reset will not affect the UDC. Additionally, the contents of the EEPROM will not be reloaded. This reset will not cause the USB PHY to be disconnected. This bit clears after the reset sequence has completed.</p> | SC | 0b |
| 2 | <p>PHY Select (PSEL) This bit indicates whether an internal or external Ethernet PHY is being used.</p> <p>0 = Internal Ethernet PHY is used. 1 = External Ethernet PHY is used.</p> | RO | Note 7-8 |

LAN950x

| Bits | Description | Type | Default |
|------|---|------|---------|
| 1 | Burst Cap Enable (BCE) This register enables use of the burst cap register, Section 7.3.14, "Burst Cap Register (BURST_CAP)" . 0 = Burst Cap register is not used to limit the TX burst size. 1 = Burst Cap register is used to limit the TX burst size. | R/W | 0b |
| 0 | Soft Reset (SRST) Writing 1 generates a software initiated reset of the device. If an external Ethernet PHY is used, it will be reset as well. A software reset will result in the contents of the EEPROM being reloaded. While the reset sequence is in progress, the USB PHY will be disconnected. After the device has been reinitialized, it will take the PHY out of the disconnect state and be visible to the Host. | SC | 0b |

Note 7-6 The default value of this bit depends on whether a NetDetach event occurred. If set, the event occurred.

Note 7-7 The default value of this field is determined by the value of the [PHY Boost](#) field of the [Configuration Flags](#) contained within the EEPROM, if present. If no EEPROM is present, 00b is the default. A USB Reset or Lite Reset (LRST) will cause this field to be restored to the image value last loaded from EEPROM, or to be set to 00b if no EEPROM is present.

Note 7-8 The PHY_SEL pin determines the default value.

7.3.6 RECEIVE FIFO INFORMATION REGISTER (RX_FIFO_INF)

Address: 018h Size: 32 bits

| Bits | Description | Type | Default |
|-------|---|------|---------|
| 31:16 | RESERVED | RO | - |
| 15:0 | RX Data FIFO Used Space (RXDUSED) Reads the amount of space in bytes used in the RX Data FIFO. For each receive frame, this field is incremented by the length of the receive data rounded up to the nearest DWORD (if the payload does not end on a DWORD boundary). | RO | 0000h |

LAN950x

7.3.7 TRANSMIT FIFO INFORMATION REGISTER (TX_FIFO_INF)

Address: 01Ch Size: 32 bits

| Bits | Description | Type | Default |
|-------|--|------|---------|
| 31:16 | RESERVED | RO | - |
| 15:0 | TX Data FIFO Free Space (TDFREE) Reads the amount of space, in bytes, available in the TX Data FIFO. | RO | 2000h |

7.3.8 POWER MANAGEMENT CONTROL REGISTER (PMT_CTL)

Address: 020h Size: 32 bits

This register controls the power management features.

| Bits | Description | Type | Default |
|-------|--|------|---------|
| 31:10 | RESERVED | RO | - |
| 9 | <p>Resume Clears Remote Wakeup Status (RES_CLR_WKP_STS) When set, the Remote Wakeup Frame Received (WUFR) and Magic Packet Received (MPFR) status signals in the MAC WUCSR will clear upon the completion of a resume sequence.</p> <p>When set, this bit also affects the WUPS field. WUPS[1] will clear upon completion of a resume event.</p> <p>Only resume sequences initiated by a wakeup frame or magic packet are affected by RES_CLR_WKP_STS.</p> <p>When cleared, the wakeup status signals are not cleared after a resume.</p> | R/W | 0b |
| 8 | <p>Resume Clears Remote Wakeup Enables (RES_CLR_WKP_EN) when asserted, all wakeup enable bits are cleared after a resume sequence, initiated from a remote wakeup, completes. Resumes initiated by the host do not clear the wakeup enables.</p> | R/W | 1b |
| 7 | <p>Device Ready (READY) When set, this bit indicates that the device is in the NORMAL state and the initial hardware configuration of the device has completed.</p> <p>Note 1: This bit is useful for events (USB Reset) that do not trigger a soft disconnect.</p> <p>2: In the case where no PHY clocks are present to complete a system reset this bit will not be set until the watchdog timer expires. This is applicable for a Lite Reset and when transitioning to the Normal Configured state.</p> | RO | 0b |
| 6:5 | <p>Suspend Mode (SUSPEND_MODE) Indicates which suspend power state to use after the Host suspends the device.</p> <p>If the device is deconfigured, it transitions to the NORMAL Unconfigured state and this register will reset to the value 10b.</p> <p>SUSPEND_MODE encoding:</p> <p>00 = SUSPEND0 01 = SUSPEND1 10 = SUSPEND2 11 = Note 7-9</p> <p>Note: It is not valid to select any suspend variant besides SUSPEND2 when in the NORMAL Unconfigured state.</p> | R/W | 10b |
| 4 | <p>PHY Reset (PHY_RST) Writing a '1' to this bit resets the PHY. The internal logic automatically holds the PHY reset for a minimum of 2 ms. When the PHY is released from reset, this bit is automatically cleared. All writes to this bit are ignored while this bit is high.</p> <p>Note: The device will NAK all USB transfers until the PHY reset completes.</p> | SC | 0b |
| 3 | <p>Wake-On-Lan Enable (WOL_EN) Enables WOL as a wakeup event.</p> | R/W | 0b |

LAN950x

| Bits | Description | Type | Default |
|------|---|------|---------|
| 2 | Energy-Detect Enable (ED_EN) Enables Energy-Detect as a wakeup event. | R/W | 0b |
| 1:0 | Wakeup Status (WUPS) This field indicates the cause of the current wakeup event. The WUPS field (both bits) are cleared by writing a 1 to either, or both bits. The encoding of these bits is as follows: 00 = No wakeup event detected 01 = Energy-Detect 10 = Wake-On-LAN / "Good Frame" (SUSPEND3) Note 7-10 11 = Indicates multiple events occurred The WUPS field will not be set unless the corresponding event is enabled prior to entering the reduced power state. If the RES_CLR_WKP_STS bit is set, WUPS[1] will clear upon completion of a resume. See the RES_CLR_WKP_STS bit for further details. Note: It is not valid to simultaneously clear the WUPS bits and change the contents of the Suspend Mode (SUSPEND_MODE) field. | R/WC | 00b |

Note 7-9 (LAN9500/LAN9500i ONLY): SUSPEND2
(LAN9500A/LAN9500Ai ONLY): SUSPEND3

Note 7-10 Good Frame and SUSPEND3 state are supported only by LAN9500A/LAN9500Ai.

7.3.9 LED GENERAL PURPOSE IO CONFIGURATION REGISTER (LED_GPIO_CFG)

Address: 024h Size: 32 bits

This register configures the external GPIO[10:8] pins.

In order for a GPIO to function as a wake event or interrupt source, it must be configured as an input. GPIO pins used to generate wake events must also be enabled by the GPIO_WAKE register, see [Section 7.3.20, "General Purpose IO Wake Enable and Polarity Register \(GPIO_WAKE\)"](#).

| Bits | Description | Type | Default | | | | | | | | | | | | | | | | | |

| 15:11 | RESERVED | RO | - |
| 10:8 | GPIO Buffer Type (GPBUF[10:8]) When set, the output buffer for the corresponding GPIO signal is configured as a push/pull driver. When cleared, the corresponding GPIO signal is configured as an open-drain driver. Bits are assigned as follows: GPBUF8 – bit 8 GPBUF9 – bit 9 GPBUF10 – bit 10 | R/W | 000b |
| 7 | RESERVED | RO | - |
| 6:4 | GPIO Direction (GPDIR[10:8]) When set, enables the corresponding GPIO as an output. When cleared the GPIO is enabled as an input. Bits are assigned as follows: GPDIR8 – bit 4 GPDIR9 – bit 5 GPDIR10 – bit 6 | R/W | 000b |
| 3 | RESERVED | RO | - |
| 2:0 | GPIO Data (GPD[10:8]) When enabled as an output, the value written is reflected on GPIO _n . When read, GPIO _n reflects the current state of the corresponding GPIO pin. Bits are assigned as follows: GPD8 – bit 0 GPD9 – bit 1 GPD10 – bit 2 | R/W | Note 7-14 |

Note 7-11 The default value for this bit is 0 when no EEPROM is present. If a EEPROM is present, the default value is the value of the [LED Select](#) bit in the [Configuration Flags](#) of the EEPROM. A USB Reset or Lite Reset (LRST) will cause this bit to be restored to the image value last loaded from EEPROM, or to be set to 0 if no EEPROM is present.

Note 7-12 (LAN9500/LAN9500i ONLY):
nLNKA_LED (Ethernet link activity LED)

(LAN9500A/LAN9500Ai ONLY):
Determined by [LED Select \(LED_SEL\)](#) setting.

Note 7-13 (LAN9500/LAN9500i ONLY):
nFDX_LED (Ethernet full-duplex LED)

(LAN9500A/LAN9500Ai ONLY):
Determined by [LED Select \(LED_SEL\)](#) setting.

Note 7-14 The default value depends on the state of the GPIO pin.

7.3.10 GENERAL PURPOSE IO CONFIGURATION REGISTER (GPIO_CFG)

Address: 028h Size: 32 bits

This register configures GPIOs 0-7. These GPIOs are not available when using external MII mode. See the [PHY_SEL](#) pin in [Table 3-4, "Miscellaneous Pins"](#).

In order for a GPIO to function as a wake event or interrupt source, it must be configured as an input. GPIOs used as wake events must also be enabled by the GPIO_WAKE register, see [Section 7.3.20, "General Purpose IO Wake Enable and Polarity Register \(GPIO_WAKE\)"](#).

| Bits | Description | Type | Default |
|-------|--|------|---------|
| 31:24 | <p>GPIO Enable 0-7 (GPIOENn) A '1' sets the associated pin to use the default function. | 7:0 | GPIO Data 0-7 (GPIODn) When enabled as an output, the value written is reflected on GPIO _n . When read, GPIOD _n reflects the current state of the corresponding GPIO pin. GPIOD0 - bit 0 GPIOD1 - bit 1 GPIOD2 - bit 2 GPIOD3 - bit 3 GPIOD4 - bit 4 GPIOD5 - bit 5 GPIOD6 - bit 6 GPIOD7 - bit 7 | R/W | Note 7-15 |

Note 7-15 The default value depends on the state of the GPIO pin.

7.3.11 AUTOMATIC FLOW CONTROL CONFIGURATION REGISTER (AFC_CFG)

Address: 02Ch Size: 32 bits

This register configures the mechanism that controls both the automatic, and software-initiated transmission of pause frames and back pressure. Refer to [Section 5.5.1, "Flow Control," on page 56](#) for more information on flow control operation.

Note: The device will not transmit pause frames or assert back pressure if the transmitter is disabled.

| Bits | Description | Type | Default |
|-------|---|------|---------|
| 31:24 | RESERVED | RO | - |
| 23:16 | <p>Automatic Flow Control High Level (AFC_HI) Specifies, in multiples of 64 bytes, the level at which flow control will trigger. When this limit is reached, the chip will apply back pressure or will transmit a pause frame, as programmed in bits [3:0] of this register.</p> <p>During full-duplex operation, only a single pause frame is transmitted when this level is reached. The pause time transmitted in this frame is programmed in the Pause Time (FCPT) field of the Flow Control Register (FLOW), contained in the MAC CSR space.</p> <p>During half-duplex operation, each incoming frame that matches the criteria in bits [3:0] of this register will be jammed for the period set in the BACK_DUR field.</p> | R/W | 00h |
| 15:8 | <p>Automatic Flow Control Low Level (AFC_LO) Specifies, in multiples of 64 bytes, the level at which a pause frame is transmitted with a pause time setting of zero. When the amount of data in the RX Data FIFO falls below this level, the pause frame is transmitted. A pause time value of zero instructs the other transmitting device to immediately resume transmission. The zero time pause frame will only be transmitted if the RX Data FIFO had reached the AFC_HI level and a pause frame was sent. A zero pause time frame is sent whenever automatic flow control is enabled in bits [3:0] of this register.</p> | R/W | 00h |

LAN950x

| Bits | Description | Type | Default |
|------|--|------|---------|
| 7:4 | <p>Back pressure Duration (BACK_DUR) This field is used to select the time period for the Back pressure Duration Timer. This field has no function in full-duplex mode.</p> <p>Note: Back pressure Duration is slightly greater in 10Mbps mode.</p> <p>Back pressure Duration</p> <p>100 Mbps Mode:</p> <p>0h = 5 us 1h = 10 us 2h = 15 us 3h = 25 us 4h = 50 us 5h = 100 us 6h = 150 us 7h = 200 us 8h = 250 us 9h = 300 us Ah = 350 us Bh = 400 us Ch = 450 us Dh = 500 us Eh = 550 us Fh = 600 us</p> <p>10 Mbps Mode:</p> <p>0h = 7.2 us 1h = 12.2 us 2h = 17.2 us 3h = 27.2 us 4h = 52.2 us 5h = 102.2 us 6h = 152.2 us 7h = 202.2 us 8h = 252.2 us 9h = 302.2 us Ah = 352.2 us Bh = 402.2 us Ch = 452.2 us Dh = 502.2 us Eh = 552.2 us Fh = 602.2 us</p> | R/W | 0h |
| 3 | <p>Flow Control on Multicast Frame (FCMULT) When this bit is set, the device will assert back pressure when the AFC level is reached and a multicast frame is received. This field has no function in full-duplex mode.</p> | R/W | 0b |
| 2 | <p>Flow Control on Broadcast Frame (FCBRD) When this bit is set, the device will assert back pressure when the AFC level is reached and a broadcast frame is received. This field has no function in full-duplex mode.</p> | R/W | 0b |
| 1 | <p>Flow Control on Address Decode (FCADD) When this bit is set, the device will assert back pressure when the AFC level is reached and a frame addressed to the device is received. This field has no function in full-duplex mode.</p> | R/W | 0b |

| Bits | Description | Type | Default |
|------|--|------|---------|
| 0 | <p>Flow Control on Any Frame (FCANY)</p> <p>When this bit is set, the device will assert back pressure, or transmit a pause frame when the AFC level is reached and any frame is received. Setting this bit enables full-duplex flow control when the device is operating in full-duplex mode.</p> <p>When this mode is enabled during half-duplex operation, the Flow Controller does not decode the MAC address and will send a pause frame upon receipt of a valid preamble (i.e., immediately at the beginning of the next frame after the RX Data FIFO level is reached).</p> <p>When this mode is enabled during full-duplex operation, the Flow Controller will immediately instruct the MAC to send a pause frame when the RX Data FIFO level is reached. The MAC will queue the pause frame transmission for the next available window.</p> <p>Setting this bit overrides bits [3:1] of this register.</p> | R/W | 0b |

LAN950x

7.3.12 EEPROM COMMAND REGISTER (E2P_CMD)

Address: 030h Size: 32 bits

This register is used to control the read and write operations on the Serial EEPROM.

| Bits | Description | Type | Default |
|------|--|------|---------|
| 31 | EPC Busy When a "1" is written into this bit, the operation specified in the EPC Command field is performed at the specified EEPROM address. This bit will remain set until the operation is complete. In the case of a read, this means that the Host can read valid data from the E2P Data register. The E2P_CMD and E2P_DATA registers should not be modified until this bit is cleared. In the case where a write is attempted and an EEPROM is not present, the EPC Busy remains busy until the EPC Time-out occurs. At that time, the busy bit is cleared. Note: EPC busy will be high immediately following power-up, chip-level, or USB reset. After the EEPROM controller has finished reading (or attempting to read) the USB Descriptors and Ethernet default register values, the EPC Busy bit is cleared. | SC | 0b |

| Bits | Description | Type | Default |
|-------|--|------|---------|
| 30:28 | <p>EPC Command This field is used to issue commands to the EEPROM controller. The EPC will execute commands when the EPC Busy bit is set. A new command must not be issued until the previous command completes. This field is encoded as follows:</p> <p>000 = READ 001 = EWDS 010 = EWEN 011 = WRITE 100 = WRAL 101 = ERASE 110 = ERAL 111 = RELOAD</p> <p>READ (Read Location): This command will cause a read of the EEPROM location pointed to by EPC Address. The result of the read is available in the E2P_DATA register.</p> <p>EWDS (Erase/Write Disable): After issued, the EEPROM will ignore erase and write commands. To re-enable erase/write operations, issue the EWEN command.</p> <p>EWEN (Erase/Write Enable): Enables the EEPROM for erase and write operations. The EEPROM will allow erase and write operations until the Erase/Write Disable command is sent, or until power is cycled.</p> <p>Note: The EEPROM device will power-up in the erase/write-disabled state. Any erase or write operations will fail until an Erase/Write Enable command is issued.</p> <p>WRITE (Write Location): If erase/write operations are enabled in the EEPROM, this command will cause the contents of the E2P_DATA register to be written to the EEPROM location selected by the EPC Address field.</p> <p>WRAL (Write All): If erase/write operations are enabled in the EEPROM, this command will cause the contents of the E2P_DATA register to be written to every EEPROM memory location.</p> <p>ERASE (Erase Location): If erase/write operations are enabled in the EEPROM, this command will erase the location selected by the EPC Address field.</p> <p>ERAL (Erase All): If erase/write operations are enabled in the EEPROM, this command will initiate a bulk erase of the entire EEPROM.</p> <p>RELOAD (Data Reload): Instructs the EEPROM controller to reload the data from the EEPROM. If a value of A5h is not found in the first address of the EEPROM, the EEPROM is assumed to be un-programmed and the Reload operation will fail. The "Data Loaded" bit indicates a successful load of the data.</p> <p>Note: A failed reload operation will result in no change to descriptor information or register contents. These items will not be set to default values as a result of the reload failure.</p> | R/W | 000b |
| 27:11 | RESERVED | RO | - |

LAN950x

| Bits | Description | Type | Default |
|------|---|------|---------|
| 10 | EPC Time-out If an EEPROM operation is performed, and there is no response from the EEPROM within 30mS, the EEPROM controller will time-out and return to its idle state. This bit is set when a time-out occurs, indicating that the last operation was unsuccessful. Note: If the EEDI pin is pulled-high (default if left unconnected), EPC commands will not time out if the EEPROM device is missing. In this case, the EPC Busy bit will be cleared as soon as the command sequence is complete. It should also be noted that the ERASE, ERAL, WRITE and WRAL commands are the only EPC commands that will time-out if an EEPROM device is not present and the EEDI signal is pulled low. | R/WC | 0 |
| 9 | Data Loaded When set, this bit indicates that a valid EEPROM was found, and that the USB and Ethernet Data programming has completed normally. This bit is set after a successful load of the data after power-up, or after a RELOAD command has completed. | R/WC | 0 |
| 8:0 | EPC Address The 9-bit value in this field is used by the EEPROM Controller to address a specific memory location in the Serial EEPROM. This is a BYTE aligned address. | R/W | 00h |

7.3.13 EEPROM DATA REGISTER (E2P_DATA)

Address: 034h Size: 32 bits

This register is used in conjunction with the E2P_CMD register to perform read and write operations to the Serial EEPROM.

| Bits | Description | Type | Default |
|------|---|------|---------|
| 31:8 | RESERVED | RO | - |
| 7:0 | EEPROM Data Value read from or written to the EEPROM. | R/W | 00h |

LAN950x

7.3.14 BURST CAP REGISTER (BURST_CAP)

Address: 038h Size: 32 bits

This register is used to limit the size of the data burst transmitted by the UTX. When more than the amount specified in the BURST_CAP register is transmitted, the UTX will send a ZLP.

Note: This register must be enabled through the [Section 7.3.5, "Hardware Configuration Register \(HW_CFG\)"](#).

| Bits | Description | Type | Default |
|------|---|------|---------|
| 31:8 | RESERVED | RO | - |
| 7:0 | BURST_CAP The maximum amount of contiguous data that may be transmitted by the UTX before a ZLP is sent. This field has units of 512 bytes for HS mode and 64 bytes for FS mode. Note: A value less than or equal to 4 in HS mode or less than or equal to 32 in FS mode indicates that burst cap enforcement is disabled. In this case, the UTX always responds to In Tokens with a ZLP when the Bulk In Empty Response (BIR) bit in the Hardware Configuration Register (HW_CFG) is deasserted. It will respond with NAKs if the Bulk In Empty Response (BIR) bit is set. | R/W | 00h |

7.3.15 DATA PORT SELECT REGISTER (DP_SEL)

Address: 040h Size: 32 bits

Before accessing the internal RAMs, the TESTEN bit must be set. It is not valid to use the RAM data port during run time. The RAM Test Mode Select chooses which internal RAM to access.

The Data Port Ready bit indicates when the data port RAM access has completed. In the case of a read operation, this indicates when the read data has been stored in the DP_DATA register.

| Bits | Description | Type | Default |
|------|---|------|---------|
| 31 | Data Port Ready (DPRDY) 0 = data port is busy processing a transaction 1 = data port is ready | RO | 1b |
| 30:3 | RESERVED | RO | - |
| 2:1 | RAM Test Select (RSEL) Selects which RAM to access. 00 = FCT Data RAM 01 = EEPROM storage RAM 10 = TX TLI RAM 11 = RX TLI RAM | R/W | 0b |
| 0 | RAM Test Mode Enable (TESTEN) Put all test accessible RAMs in test mode. | R/W | 0b |

LAN950x

7.3.16 DATA PORT COMMAND REGISTER (DP_CMD)

Address: 044h Size: 32 bits

This register commences the data port access. Writing a one to this register will enable a write access, while writing a zero will do a read access.

The address and data registers need to be configured appropriately for the desired read or write operation before accessing this register.

| Bits | Description | Type | Default |
|------|--|------|---------|
| 31:1 | RESERVED | RO | - |
| 0 | Data Port Write. Selects operation. Writing to this bit initiates the data port access. 0 = read operation 1 = write operation | R/W | 0b |

7.3.17 DATA PORT ADDRESS REGISTER (DP_ADDR)

Address: 048h Size: 32 bits

Indicates the address to be used for the data port access.

| Bits | Description | Type | Default |
|-------|---|------|---------|
| 31:15 | RESERVED | RO | - |
| 14:0 | Data Port Address[14:0] Note: This quantity specifies a DWORD address. | R/W | 0000h |

LAN950x

7.3.18 DATA PORT DATA 0 REGISTER (DP_DATA0)

Address: 04Ch Size: 32 bits

The Data Port Data register holds the write data for a write access and the resultant read data for a read access. Before reading this register for the result of a read operation, the Data Port Ready bit should be checked. The Data Port Ready bit must indicate the data port is ready. Otherwise the read operation is still in progress.

| Bits | Description | Type | Default |
|------|------------------------------|------|------------|
| 31:0 | Data Port Data [31:0] | R/W | 0000_0000h |

7.3.19 DATA PORT DATA 1 REGISTER (DP_DATA1)

Address: 050h Size: 32 bits

The Data Port Data register holds the write data for a write access and the resultant read data for a read access.

Before reading the this register for the result of a read operation, the Data Port Ready bit should be checked. The Data Port Ready bit must indicate the data port is ready. Otherwise the read operation is still in progress.

This register required when accessing the RX TLI and TX TLI RAMs. These RAMs have a width of 37 bits.

| Bits | Description | Type | Default |
|------|-------------------------------|------|---------|
| 31:5 | RESERVED | RO | - |
| 4:0 | Data Port Data [36:32] | R/W | 00h |

LAN950x

7.3.20 GENERAL PURPOSE IO WAKE ENABLE AND POLARITY REGISTER (GPIO_WAKE)

Address: 064h Size: 32 bits

This register enables the GPIOs to function as wake events for the device when asserted. It also allows the polarity used for a wake event/interrupt to be configured.

Note: GPIOs must not cause a wake event to the device when not configured as a GPIO.

| Bits | Description | Type | Default |
|-------|--|------|---------------------------|
| 31 | <p>(LAN9500A/LAN9500Ai ONLY, Otherwise RESERVED)</p> <p>PHY Link Up Enable (PHY_LINKUP_EN) Setting this bit enables the use of GPIO7 to signal a PHY Link Up event when in SUSPEND0 or SUSPEND 3 state. In addition to setting this bit, the parameters for GPIO7 must be set as discussed in Section 5.12.2.4, "Enabling PHY Link Up Wake Events (LAN9500A/LAN9500Ai ONLY)," on page 108 in order for signaling to occur.</p> | R/W | 0b |
| 30:27 | RESERVED | RO | - |
| 26:16 | <p>GPIO Polarity 0-10 (GPIOPOLn)</p> <p>0 = Wakeup/interrupt is triggered when GPIO is driven low 1 = Wakeup/interrupt is triggered when GPIO is driven high</p> <p>GPIOPOL0 - bit 16 GPIOPOL1 - bit 17 GPIOPOL2 - bit 18 GPIOPOL3 - bit 19 GPIOPOL4 - bit 20 GPIOPOL5 - bit 21 GPIOPOL6 - bit 22 GPIOPOL7 - bit 23 GPIOPOL8 - bit 24 GPIOPOL9 - bit 25 GPIOPOL10 - bit 26</p> | R/W | 000h |
| 15:11 | RESERVED | RO | - |
| 10:0 | <p>GPIO Wake 0-10 (GPIOWKn)</p> <p>0 = The GPIO can not wake up the device. 1 = The GPIO can trigger a wake up event.</p> <p>GPIOWK0 - bit 0 GPIOWK1 - bit 1 GPIOWK2 - bit 2 GPIOWK3 - bit 3 GPIOWK4 - bit 4 GPIOWK5 - bit 5 GPIOWK6 - bit 6 GPIOWK7 - bit 7 GPIOWK8 - bit 8 GPIOWK9 - bit 9 GPIOWK10 - bit 10</p> <p>Note: (LAN9500A/LAN9500Ai ONLY): This field is protected by Reset Protection (RST_PROTECT).</p> | R/W | Note 7-16 |

Note 7-16 (LAN9500/LAN9500i ONLY): 000h

(LAN9500A/LAN9500Ai ONLY):

The default value of this field is loaded from the associated bytes of the EEPROM. The high order unused bits of the EEPROM are ignored. If no EEPROM is present, the default value of each bit in the field is 0. A USB Reset or Lite Reset (LRST) will cause this field to be restored to the image value last loaded from EEPROM, or will cause the value of each bit to be set to 0 if no EEPROM is present.

7.3.21 INTERRUPT ENDPOINT CONTROL REGISTER (INT_EP_CTL)

Address: 068h Size: 32 bits

This register determines which events cause status to be reported by the interrupt endpoint. See [Section 5.3.1.3, "Endpoint 3 \(Interrupt\)"](#) for more details.

| Bits | Description | Type | Default |
|-------|---|------|---------|
| 31 | Interrupt Endpoint Always On (INTEP_ON) When this bit is set, an interrupt packet will always be sent at the interrupt endpoint interval. 0 = Only allow the transmission of an interrupt packet when an interrupt source is enabled and occurs. 1 = Always transmit an interrupt packet at the interrupt interval. | R/W | 0b |
| 30:20 | RESERVED | RO | - |
| 19 | MAC Reset Time Out (MACRTO_EN) 0 = This event can not cause an interrupt packet to be issued. 1 = This event can cause an interrupt packet to be issued. | R/W | 0b |

| 10:0 | TX FIFO Write Pointer (TXWRPTR) Current value of TX FIFO write pointer (DWORD address). | RO | 000h |

7.3.27 HS DESCRIPTOR ATTRIBUTES REGISTER (HS_ATTR)

This register is supported only by LAN9500A/LAN9500Ai.

Address: 0A0h Size: 32 bits

This register sets the length values for HS descriptors that have been loaded into Descriptor RAM via the Data Port registers. The HS Polling interval is also defined by a field within this register. The Descriptor RAM images may be used, in conjunction with this register, to facilitate customized operation when no EEPROM is present.

- Note 1:** If a descriptor does not exist in Descriptor RAM, its size value must be written as 00h.
- 2:** This register only affects system operation when an EEPROM is not present and the [EEPROM Emulation Enable \(EEM\)](#) bit indicates Descriptor RAM and the Attributes Registers are to be used for descriptor processing.
- 3:** Writing to this register when an EEPROM is present is prohibited and will result in untoward operation and unexpected results.
- 4:** This register is protected by [Reset Protection \(RST_PROTECT\)](#).

| Bits | Description | Type | Default |
|-------|---|------|---------|
| 31:24 | RESERVED | RO | - |
| 23:16 | HS Polling Interval (HS_POLL_INT) | R/W | 04h |
| 15:8 | HS Device Descriptor Size (HS_DEV_DESC_SIZE) Note 7-17 | R/W | 00h |
| 7:0 | HS Configuration Descriptor Size (HS_CFG_DESC_SIZE) Note 7-18 | R/W | 00h |

Note 7-17 The only legal values are 0 and 0x12h. Writing any other values will result in untoward behavior and unexpected results.

Note 7-18 The only legal values are 0 and 0x12h. Writing any other values will result in untoward behavior and unexpected results.

LAN950x

7.3.28 FS DESCRIPTOR ATTRIBUTES REGISTER (FS_ATTR)

This register is supported only by LAN9500A/LAN9500Ai.

Address: 0A4h Size: 32 bits

This register sets the length values for FS descriptors that have been loaded into Descriptor RAM via the Data Port registers. The FS Polling interval is also defined by a field within this register. The Descriptor RAM images may be used, in conjunction with this register, to facilitate customized operation when no EEPROM is present.

- Note 1:** If a descriptor does not exist in Descriptor RAM, its size value must be written as 00h.
- 2:** This register only affects system operation when an EEPROM is not present and the [EEPROM Emulation Enable \(EEM\)](#) bit indicates Descriptor RAM and the Attributes Registers are to be used for descriptor processing.
- 3:** Writing to this register when an EEPROM is present is prohibited and will result in untoward operation and unexpected results.
- 4:** This register is protected by [Reset Protection \(RST_PROTECT\)](#).

| Bits | Description | Type | Default |
|-------|---|------|---------|
| 31:24 | RESERVED | RO | - |
| 23:16 | FS Polling Interval (FS_POLL_INT) | R/W | 01h |
| 15:8 | FS Device Descriptor Size (FS_DEV_DESC_SIZE) Note 7-19 | R/W | 00h |
| 7:0 | FS Configuration Descriptor Size (FS_CFG_DESC_SIZE) Note 7-20 | R/W | 00h |

Note 7-19 The only legal values are 0 and 0x12h. Writing any other values will result in untoward behavior and unexpected results.

Note 7-20 The only legal values are 0 and 0x12h. Writing any other values will result in untoward behavior and unexpected results.

7.3.29 STRING DESCRIPTOR ATTRIBUTES REGISTER 0 (STRNG_ATTR0)

This register is supported only by LAN9500A/LAN9500Ai.

Address: 0A8h Size: 32 bits

This register sets the length values for the named string descriptors that have been loaded into Descriptor RAM via the Data Port registers. The Descriptor RAM images may be used, in conjunction with this register, to facilitate customized operation when no EEPROM is present.

- Note 1:** If a descriptor does not exist in Descriptor RAM, its size value must be written as 00h.
- 2:** This register only affects system operation when an EEPROM is not present and the [EEPROM Emulation Enable \(EEM\)](#) bit indicates Descriptor RAM and the Attributes Registers are to be used for descriptor processing.
- 3:** Writing to this register when an EEPROM is present is prohibited and will result in untoward operation and unexpected results.
- 4:** This register is protected by [Reset Protection \(RST_PROTECT\)](#).

| Bits | Description | Type | Default |
|-------|--|------|---------|
| 31:24 | Configuration String Descriptor Size (CFGSTR_DESC_SIZE) | R/W | 00h |
| 23:16 | Serial Number String Descriptor Size (SERSTR_DESC_SIZE) | R/W | 00h |
| 15:8 | Product Name String Descriptor Size (PRODSTR_DESC_SIZE) | R/W | 00h |
| 7:0 | Manufacturing String Descriptor Size (MANUF_DESC_SIZE) | R/W | 00h |

LAN950x

7.3.30 STRING DESCRIPTOR ATTRIBUTES REGISTER 1 (STRNG_ATTR1)

This register is supported only by LAN9500A/LAN9500Ai.

Address: 0ACh Size: 32 bits

This register sets the length values for the named string descriptors that have been loaded into Descriptor RAM via the Data Port registers. The Descriptor RAM images may be used, in conjunction with this register, to facilitate customized operation when no EEPROM is present.

- Note 1:** If a descriptor does not exist in Descriptor RAM, its size value must be written as 00h.
- 2:** This register only affects system operation when an EEPROM is not present and the [EEPROM Emulation Enable \(EEM\)](#) bit indicates Descriptor RAM and the Attributes Registers are to be used for descriptor processing.
 - 3:** Writing to this register when an EEPROM is present is prohibited and will result in untoward operation and unexpected results.
 - 4:** This register is protected by [Reset Protection \(RST_PROTECT\)](#).

| Bits | Description | Type | Default |
|------|---|------|---------|
| 31:8 | RESERVED | RO | - |
| 7:0 | Interface String Descriptor Size (INTSTR_DESC_SIZE) | R/W | 00h |

7.3.31 FLAG ATTRIBUTES REGISTER (FLAG_ATTR)

This register is supported only by LAN9500A/LAN9500Ai.

Address: 0B0h Size: 32 bits

This register sets the values of elements of the Configuration Flags and PME flags when no EEPROM is present and customized operation, using Descriptor RAM images, is to occur. This register does not contain Configuration Flag elements that are components of other registers. Those elements will be programmed by the driver software directly prior to initiating customized operation via Descriptor RAM.

- Note 1:** This register only affects system operation when an EEPROM is not present and the [EEPROM Emulation Enable \(EEM\)](#) bit indicates Descriptor RAM and the Attributes Registers are to be used for descriptor processing.
- 2:** Writing to this register when an EEPROM is present is prohibited and will result in untoward operation and unexpected results.
- 3:** This register is protected by [Reset Protection \(RST_PROTECT\)](#).

| Bits | Description | Type | Default |
|-------|---|------|---------------------------|
| 31:18 | RESERVED | RO | - |
| 17 | Remote Wakeup Support (RMT_WKP) Refer to Remote Wakeup Support bit in Table 5-58, "Configuration Flags," on page 80 for definition. | R/W | Note 7-21 |
| 16 | Power Method (PWR_SEL) Refer to Power Method bit in Table 5-58, "Configuration Flags," on page 80 for definition. | R/W | Note 7-22 |
| 15:8 | RESERVED | RO | - |
| 7:0 | GPIO PME Flags (PME_FLAGS) Refer to Table 5-59, "GPIO PME Flags," on page 81 for bit definitions. | R/W | 00h |

Note 7-21 The default value depends on the setting of the [RMT_WKP](#) strap.

Note 7-22 The default value depends on the setting of the [PWR_SEL](#) strap.

LAN950x

7.4 MAC Control and Status Registers

Table 7-4 lists the registers contained in this section.

TABLE 7-4: MAC CONTROL AND STATUS REGISTER (MCSR) MAP

| Address | Symbol | Register Name |
|-------------|------------|--|
| 100h | MAC_CR | MAC Control Register |
| 104h | ADDRH | MAC Address High Register |
| 108h | ADDRL | MAC Address Low Register |
| 10Ch | HASHH | Multicast Hash Table High Register |
| 110h | HASHL | Multicast Hash Table Low Register |
| 114h | MII_ACCESS | MII Access Register |
| 118h | MII_DATA | MII Data Register |
| 11Ch | FLOW | Flow Control Register |
| 120h | VLAN1 | VLAN1 Tag Register |
| 124h | VLAN2 | VLAN2 Tag Register |
| 128h | WUFF | Wakeup Frame Filter Register |
| 12Ch | WUCSR | Wakeup Control and Status Register |
| 130h | COE_CR | Checksum Offload Engine Control Register |
| 134h - 1FCh | RESERVED | Reserved for future use |

7.4.1 MAC CONTROL REGISTER (MAC_CR)

Address: 100h Size: 32 bits

This register establishes the RX and TX operating modes and includes controls for address filtering and packet filtering.

| Bits | Description | Type | Default |
|-------|---|------|---------|
| 31 | Receive All Mode (RXALL) When set, all incoming packets will be received and passed on to the address filtering function for processing of the selected filtering mode on the received frame. Address filtering then occurs and is reported in Receive Status. When reset, only frames that pass Destination Address filtering will be sent to the Application. | R/W | 0b |
| 30-24 | RESERVED | RO | - |
| 23 | Disable Receive Own (RCVOWN) When set, the MAC disables the reception of frames when TXEN is asserted. The MAC blocks the transmitted frame on the receive path. When reset, the MAC receives all packets the PHY gives, including those transmitted by the MAC. This bit should be reset when the Full Duplex Mode bit is set. | R/W | 0b |
| 22 | RESERVED | RO | - |
| 21 | Loopback Operation Mode (LOOPBK) Selects the loop back operation modes for the MAC. This is only for full duplex mode 0 = Normal. No feedback 1 = Internal through MII In internal loopback mode, the TX frame is received by the Internal MII interface, and sent back to the MAC without being sent to the PHY. Note: When enabling or disabling the loopback mode, it can take up to 10µs for the mode change to occur. The transmitter and receiver must be stopped and disabled when modifying the LOOPBK bit. The transmitter or receiver should not be enabled within 10µs of modifying the LOOPBK bit. | R/W | 0b |
| 20 | Full Duplex Mode (FDPX) When set, the MAC operates in Full-Duplex mode, in which it can transmit and receive simultaneously. | R/W | 0b |
| 19 | Pass All Multicast (MCPAS) When set, indicates that all incoming frames with a Multicast destination address (first bit in the destination address field is 1) are received. Incoming frames with physical address (Individual Address/Unicast) destinations are filtered and received only if the address matches the MAC Address. | R/W | 0b |
| 18 | Promiscuous Mode (PRMS) When set, indicates that any incoming frame is received regardless of its destination address. | R/W | 1b |
| 17 | Inverse filtering (INVFLT) When set, the address check Function operates in Inverse filtering mode. This is valid only during Perfect filtering mode. | R/W | 0b |
| 16 | Pass Bad Frames (PASSBAD) When set, all incoming frames that passed address filtering are received, including runt frames, collided frames or truncated frames caused by buffer underrun. | R/W | 0b |
| 15 | Hash Only Filtering mode (HO) When set, the address check Function operates in the imperfect address filtering mode both for physical and multicast addresses. | R/W | 0b |
| 14 | RESERVED | RO | - |

LAN950x

| Bits | Description | Type | Default |
|------|---|------|---------|
| 13 | <p>Hash/Perfect Filtering Mode (HPFILT) When reset (0), the device will implement a perfect address filter on incoming frames, according the address specified in the MAC address register.</p> <p>When set (1), the address check function does imperfect address filtering of multicast incoming frames according to the hash table specified in the multicast hash table register.</p> <p>If the Hash Only Filtering mode (HO) bit is set (1), then the physical (IA) are imperfect filtered too. If the Hash Only Filtering mode (HO) bit is reset (0), then the IA addresses are perfect address filtered according to the MAC Address register</p> | R/W | 0b |
| 12 | <p>Late Collision Control (LCOLL) When set, enables retransmission of the collided frame even after the collision period (late collision). When reset, the MAC disables frame transmission on a late collision. In any case, the Late Collision status is appropriately updated in the Transmit Packet status.</p> | R/W | 0b |
| 11 | <p>Disable Broadcast Frames (BCAST) When set, disables the reception of broadcast frames. When reset, forwards all broadcast frames to the application.</p> <p>Note: When wakeup frame detection is enabled via the Wakeup Frame Enable (WUEN) bit of the Wakeup Control and Status Register (WUCSR), a broadcast wakeup frame will wake up the device despite the state of this bit.</p> | R/W | 0b |
| 10 | <p>Disable Retry (DISRTY) When set, the MAC attempts only one transmission. When a collision is seen on the bus, the MAC ignores the current frame and goes to the next frame and a retry error is reported in the Transmit status. When reset, the MAC attempts 16 transmissions before signaling a retry error.</p> | R/W | 0b |
| 9 | RESERVED | RO | - |
| 8 | <p>Automatic Pad Stripping (PADSTR) When set, the MAC strips the pad field on all incoming frames, if the length field is less than 46 bytes. The FCS field is also stripped, since it is computed at the transmitting station based on the data and pad field characters, and is invalid for a received frame that has had the pad characters stripped. Receive frames with a 46-byte or greater length field are passed to the Application unmodified (FCS is not stripped). When reset, the MAC passes all incoming frames to system memory unmodified.</p> | R/W | 0b |

| Bits | Description | Type | Default | | | | | | | | | | |
|-------------|---|-------------|-------------------------------|----|----|----|---|----|---|----|---|-----|-----|
| 7:6 | <p>BackOff Limit (BOLMT)</p> <p>The BOLMT bits allow the user to set its back-off limit in a relaxed or aggressive mode. According to IEEE 802.3, the MAC has to wait for a random number [r] of slot-times (Note 7-23) after it detects a collision, where: (eq.1) $0 < r < 2^K$</p> <p>The exponent K is dependent on how many times the current frame to be transmitted has been retried, as follows: (eq.2) $K = \min(n, 10)$ where n is the current number of retries.</p> <p>If a frame has been retried three times, then K = 3 and r = 8 slot-times maximum. If it has been retried 12 times, then K = 10, and r = 1024 slot-times maximum.</p> <p>An LFSR (linear feedback shift register) 20-bit counter emulates a 20bit random number generator, from which r is obtained. Once a collision is detected, the number of the current retry of the current frame is used to obtain K (eq.2). This value of K translates into the number of bits to use from the LFSR counter. If the value of K is 3, the MAC takes the value in the first three bits of the LFSR counter and uses it to count down to zero on every slot-time. This effectively causes the MAC to wait eight slot-times. To give the user more flexibility, the BOLMT value forces the number of bits to be used from the LFSR counter to a predetermined value as in the table below.</p> <table border="1" data-bbox="383 762 1089 989"> <thead> <tr> <th>BOLMT Value</th> <th># Bits Used from LFSR Counter</th> </tr> </thead> <tbody> <tr> <td>00</td> <td>10</td> </tr> <tr> <td>01</td> <td>8</td> </tr> <tr> <td>10</td> <td>4</td> </tr> <tr> <td>11</td> <td>1</td> </tr> </tbody> </table> <p>Thus, if the value of K = 10, the MAC will look at the BOLMT if it is 00, then use the lower ten bits of the LFSR counter for the wait countdown. If the BOLMT is 10, then it will only use the value in the first four bits for the wait countdown, etc.</p> <p>Note 7-23 Slot-time = 512 bit times. (See IEEE 802.3 Spec., Secs. 4.2.3.25 and 4.4.2.1)</p> | BOLMT Value | # Bits Used from LFSR Counter | 00 | 10 | 01 | 8 | 10 | 4 | 11 | 1 | R/W | 00b |
| BOLMT Value | # Bits Used from LFSR Counter | | | | | | | | | | | | |
| 00 | 10 | | | | | | | | | | | | |
| 01 | 8 | | | | | | | | | | | | |
| 10 | 4 | | | | | | | | | | | | |
| 11 | 1 | | | | | | | | | | | | |
| 5 | <p>Deferral Check (DFCHK)</p> <p>When set, enables the deferral check in the MAC. The MAC will abort the transmission attempt if it has deferred for more than 24,288 bit times. Deferral starts when the transmitter is ready to transmit, but is prevented from doing so because the CRS is active. Defer time is not cumulative. If the transmitter defers for 10,000 bit times, then transmits, collides, backs off, and then has to defer again after completion of back-off, the deferral timer resets to 0 and restarts. When reset, the deferral check is disabled in the MAC and the MAC defers indefinitely.</p> | R/W | 0b | | | | | | | | | | |
| 4 | RESERVED | RO | - | | | | | | | | | | |
| 3 | <p>Transmitter Enable (TXEN)</p> <p>When set, the MAC's transmitter is enabled and it will transmit frames from the buffer onto the cable. When reset, the MAC's transmitter is disabled and will not transmit any frames.</p> | R/W | 0b | | | | | | | | | | |
| 2 | <p>Receiver Enable (RXEN)</p> <p>When set (1), the MAC's receiver is enabled and will receive frames from the internal PHY. When reset, the MAC's receiver is disabled and will not receive any frames from the internal PHY.</p> | R/W | 0b | | | | | | | | | | |
| 1:0 | RESERVED | RO | - | | | | | | | | | | |

LAN950x

7.4.2 MAC ADDRESS HIGH REGISTER (ADDRH)

Address: 104h Size: 32 bits

This register contains the upper 16 bits of the physical address of the MAC, where ADDRH[15:8] is the 6th octet of the RX frame.

Note: (LAN9500A/LAN9500Ai ONLY):
This register is protected by [Reset Protection \(RST_PROTECT\)](#).

| Bits | Description | Type | Default |
|-------|---|------|---------|
| 31:16 | RESERVED | RO | - |
| 15:0 | Physical Address [47:32] This field contains the upper 16 bits (47:32) of the physical address of the device. | R/W | FFFFh |

7.4.3 MAC ADDRESS LOW REGISTER (ADDRL)

Address: 108h Size: 32 bits

This register contains the lower 32 bits of the physical address of the MAC, where ADDRL[7:0] is the first octet of the Ethernet frame.

Note: (LAN9500A/LAN9500Ai ONLY):
This register is protected by [Reset Protection \(RST_PROTECT\)](#).

| Bits | Description | Type | Default |
|------|--|------|------------|
| 31:0 | Physical Address [31:0] This field contains the lower 32 bits (32:0) of the Physical Address of this MAC device. | R/W | FFFF_FFFFh |

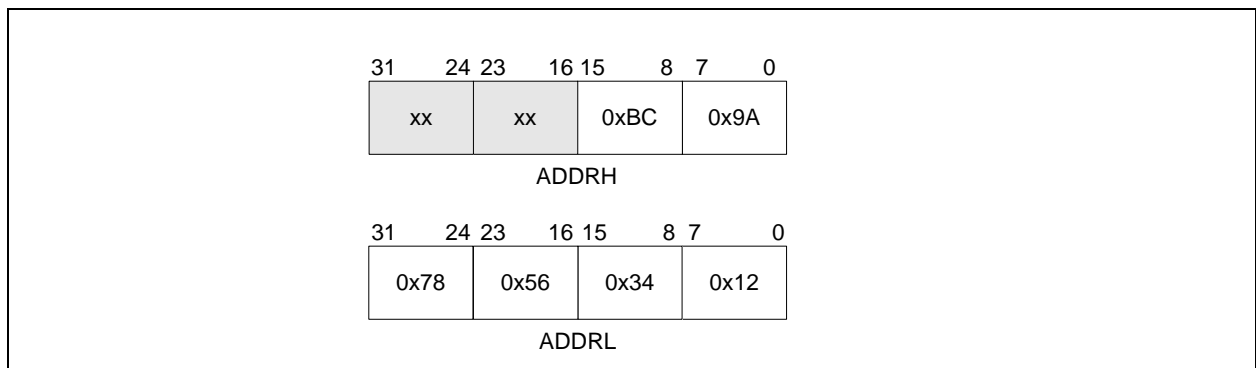

Table 7-5 illustrates the byte ordering of the ADDRL and ADDRH registers with respect to the reception of the Ethernet physical address.

TABLE 7-5: ADDRL, ADDRH BYTE ORDERING

| ADDRL, ADDRH | Order of Reception on Ethernet |
|--------------|--------------------------------|
| ADDRL[7:0] | 1 st |
| ADDRL[15:8] | 2 nd |
| ADDRL[23:16] | 3 rd |
| ADDRL[31:24] | 4 th |
| ADDRH[7:0] | 5 th |
| ADDRH[15:8] | 6 th |

As an example, if the desired Ethernet physical address is 12-34-56-78-9A-BC, the ADDRL and ADDRH registers would be programmed as shown in Figure 7-1.

FIGURE 7-1: EXAMPLE ADDRL, ADDRH ADDRESS ORDERING

LAN950x

7.4.4 MULTICAST HASH TABLE HIGH REGISTER (HASHH)

Address: 10Ch Size: 32 bits

The 64-bit Multicast table is used for group address filtering. For hash filtering, the contents of the destination address in the incoming frame is used to index the contents of the Hash table. The most significant bit determines the register to be used (Hi/Low), while the other five bits determine the bit within the register. A value of 00000 selects Bit 0 of the Multicast Hash Table Lo register and a value of 11111 selects the Bit 31 of the Multicast Hash Table Hi register.

If the corresponding bit is 1, then the multicast frame is accepted. Otherwise, it is rejected. If the "Pass All Multicast" (MCPAS) bit is set (1), then all multicast frames are accepted regardless of the multicast hash values.

The Multicast Hash Table Hi register contains the higher 32 bits of the hash table and the Multicast Hash Table Low register contains the lower 32 bits of the hash table.

| Bits | Description | Type | Default |
|------|---|------|------------|
| 31:0 | Upper 32 bits of the 64-bit Hash Table | R/W | 0000_0000h |

7.4.5 MULTICAST HASH TABLE LOW REGISTER (HASHL)

Address: 110h Size: 32 bits

This register defines the lower 32-bits of the Multicast Hash Table. Please refer to [Section 7.4.4, "Multicast Hash Table High Register \(HASHH\)," on page 164](#) for further details.

| Bits | Description | Type | Default |
|------|---|------|------------|
| 31:0 | Lower 32 bits of the 64-bit Hash Table | R/W | 0000_0000h |

LAN950x

7.4.6 MII ACCESS REGISTER (MII_ACCESS)

Address: 114h Size: 32 bits

This register is used to control the management cycles to the internal PHY.

| Bits | Description | Type | Default |
|-------|--|------|---------|
| 31:16 | RESERVED | RO | - |
| 15:11 | PHY Address For every access to this register, this field must be set to 00001b. | R/W | 00000b |
| 10:6 | MII Register Index (MIIRINDA) These bits select the desired MII register in the PHY. | R/W | 00000b |
| 5:2 | RESERVED | RO | - |
| 1 | MII Write (MIIWnR) Setting this bit tells the PHY that this will be a write operation using the MII data register. If this bit is not set, this will be a read operation, packing the data in the MII data register. | R/W | 0b |
| 0 | MII Busy (MIIBZY) This bit must be polled to determine when the MII register access is complete. This bit must read a logical 0 before writing to this register or to the MII data register. The LAN driver software must set (1) this bit in order for the Host to read or write any of the MII PHY registers. During a MII register access, this bit will be set, signifying a read or write access is in progress. The MII data register must be kept valid until the MAC clears this bit during a PHY write operation. The MII data register is invalid until the MAC has cleared this bit during a PHY read operation. | SC | 0b |

7.4.7 MII DATA REGISTER (MII_DATA)

Address: 118h Size: 32 bits

This register contains either the data to be written to the PHY register specified in the MII Access Register, or the read data from the PHY register whose index is specified in the MII Access Register. Refer to [Section 7.4.6, "MII Access Register \(MII_ACCESS\)," on page 166](#) for further details.

Note: The MIIBZY bit in the MII_ACCESS register must be cleared when writing to this register.

| Bits | Description | Type | Default |
|-------|---|------|---------|
| 31:16 | RESERVED | RO | - |
| 15:0 | MII Data This contains the 16-bit value read from the PHY read operation or the 16-bit data value to be written to the PHY before an MII write operation. | R/W | 0000h |

LAN950x

7.4.8 FLOW CONTROL REGISTER (FLOW)

Address: 11Ch Size: 32 bits

This register is used to control the generation and reception of the Control frames by the MAC's flow control block. A write to this register with busy bit set to 1 will trigger the Flow control block to generate a Control frame. Before writing to this register, the application has to make sure that the busy bit is not set.

| Bits | Description | Type | Default |
|-------|---|------|---------|
| 31:16 | Pause Time (FCPT) This field indicates the value to be used in the PAUSE TIME field in the control frame. | R/W | 0000h |
| 15:3 | RESERVED | RO | - |
| 2 | Pass Control Frames (FCPASS) When set, the MAC sets the packet filter bit in the receive packet status to indicate to the application that a valid pause frame has been received. The application must accept or discard a received frame based on the packet filter control bit. The MAC receives, decodes and performs the pause function when a valid pause frame is received in full-duplex mode and when flow control is enabled (FCEN bit set). When reset, the MAC resets the packet filter bit in the receive packet status. The MAC always passes the data of all frames it receives (including flow control frames) to the application. Frames that do not pass address filtering, as well as frames with errors, are passed to the application. The application must discard or retain the received frame's data based on the received frame's STATUS field. Filtering modes (promiscuous mode, for example) take precedence over the FCPASS bit. | R/W | 0b |
| 1 | Flow Control Enable (FCEN) When set, enables the MAC flow control function. The MAC decodes all incoming frames for control frames; if it receives a valid control frame (PAUSE command), it disables the transmitter for a specified time (Decoded pause time x slot time). When reset, the MAC flow control function is disabled; the MAC does not decode frames for control frames. Note: Flow Control is applicable when the MAC is set in full duplex mode. In half-duplex mode, this bit enables the back pressure function to control the flow of received frames to the MAC. | R/W | 0b |
| 0 | Flow Control Busy (FCBSY) This bit is set high whenever a pause frame or back pressure is being transmitted. This bit should read logical 0 before writing to the Flow Control (FLOW) register. During a transfer of Control Frame, this bit continues to be set, signifying that a frame transmission is in progress. After the PAUSE control frame's transmission is complete, the MAC resets to 0. Note 1: When writing this register the FCBSY bit must always be zero. 2: Applications must always write a zero to this bit. | R/W | 0b |

7.4.9 VLAN1 TAG REGISTER (VLAN1)

Address: 120h Size: 32 bits

This register contains the VLAN tag field to identify VLAN1 frames. For VLAN frames, the legal frame length is increased from 1518 bytes to 1522 bytes.

The RXCOE also uses this register to determine the protocol value to use to indicate the existence of a VLAN tag. When using the RXCOE, this value may only be changed if the RX path is disabled. If it is desired to change this value during run time, it is safe to do so only after the MAC is disabled and the TLI is empty.

| Bits | Description | Type | Default |
|-------|--|------|---------|
| 31:16 | RESERVED | RO | - |
| 15:0 | VLAN1 Tag Identifier (VTI1) This contains the VLAN Tag field to identify the VLAN1 frames. This field is compared with the 13 th and 14 th bytes of the incoming frames for VLAN1 frame detection. | R/W | FFFFh |

LAN950x

7.4.10 VLAN2 TAG REGISTER (VLAN2)

Address: 124h Size: 32 bits

This register contains the VLAN tag field to identify VLAN2 frames. For VLAN frames the legal frame length is increased from 1518 bytes to 1522 bytes.

| Bits | Description | Type | Default |
|-------|--|------|---------|
| 31:16 | RESERVED | RO | - |
| 15:0 | VLAN2 Tag Identifier (VTI2) This contains the VLAN Tag field to identify the VLAN2 frames. This field is compared with the 13 th and 14 th bytes of the incoming frames for VLAN2 frame detection. | R/W | FFFFh |

7.4.11 WAKEUP FRAME FILTER (WUFF)

Address: 128h Size: 32 bits

This register is used to configure the Wakeup Frame Filter.

| Bits | Description | Type | Default |
|------|--|------|------------|
| 31:0 | <p>Wakeup Frame Filter (WFF) The Wakeup Frame Filter is configured through this register using an indexing mechanism. Following a reset, the MAC loads the first value written to this location to the first DWORD in the Wakeup Frame Filter (Filter 0 Byte Mask 0). The second value written to this location is loaded to the second DWORD in the Wakeup Frame Filter (Filter 0 Byte Mask 1) and so on. Once the device dependent number of DWORDs have been written (Note 7-24), the internal pointer will once again point to the first entry and the filter entries can be modified in the same manner. Similarly, the device dependent number of DWORDS can be read sequentially to obtain the values stored in the WFF(Note 7-24). Please refer to Section 5.5.5, "Wakeup Frame Detection," on page 59 for further information concerning the Wakeup Frame Filter.</p> <p>Note: This register should be read and written using the device dependent number of consecutive DWORD operations (Note 7-24). Failure to read or write the entire contents of the WFF may cause the internal read/write pointers to be left in a position other than pointing to the first entry. A mechanism for resetting the internal pointers to the beginning of the WFF is available via the WFF Pointer Reset (WFF_PTR_RST) bit of the Wakeup Control and Status Register (WUCSR). This mechanism enables the application program to re-synchronize with the internal WFF pointers if it has not previously read/written the complete contents of the WFF.</p> | R/W | 0000_0000h |

Note 7-24 The number of DWORD read/writes is dependent on the number of wakeup frames supported by the device. DWORD read/writes required are as follow:
 (LAN9500/LAN9500i ONLY): 20 (4 filters supported)
 (LAN9500A/LAN9500Ai ONLY): 40 (8 filters supported)

LAN950x

7.4.12 WAKEUP CONTROL AND STATUS REGISTER (WUCSR)

Address: 12Ch Size: 32 bits

This register contains data pertaining to the MAC's remote wakeup status and capabilities.

| Bits | Description | Type | Default |
|-------|---|------|---------|
| 31 | WFF Pointer Reset (WFF_PTR_RST) This self-clearing bit resets the Wakeup Frame Filter (WFF) internal read and write pointers to the beginning of the WFF. | SC | 0b |
| 30:10 | RESERVED | RO | - |
| 9 | Global Unicast Wakeup Enable (GUEN) When set, the MAC wakes up from power-saving mode on receipt of a global unicast frame. A global unicast frame has the MAC Address [0] bit set to 0. Note: The Wakeup Frame Enable (WUEN) bit of this register must also be set to enable wakeup. | R/W | 0b |
| 8 | RESERVED | RO | - |
| 7 | (LAN9500A/LAN9500Ai ONLY, Otherwise RESERVED) Perfect DA Frame Received (PFDA_FR) The MAC sets this bit upon receiving a valid frame with a destination address that matches the physical address. | R/WC | 0b |
| 6 | Remote Wakeup Frame Received (WUFR) The MAC sets this bit upon receiving a valid remote Wakeup Frame. | R/WC | 0b |
| 5 | Magic Packet Received (MPR) The MAC sets this bit upon receiving a valid Magic Packet. | R/WC | 0b |
| 4 | (LAN9500A/LAN9500Ai ONLY, Otherwise RESERVED) Broadcast Frame Received (BCAST_FR) The MAC Sets this bit upon receiving a valid broadcast frame. | R/WC | 0b |
| 3 | (LAN9500A/LAN9500Ai ONLY, Otherwise RESERVED) Perfect DA Wakeup Enable (PFDA_EN) When set, remote wakeup mode is enabled and the MAC is capable of waking up on receipt of a frame with a destination address that matches the physical address of the device. The physical address is stored in the MAC Address High Register (ADDRH) and MAC Address Low Register (ADDRL) . | R/W | 0b |
| 2 | Wakeup Frame Enable (WUEN) When set, remote wakeup mode is enabled and the MAC is capable of detecting Wakeup Frames as programmed in the Wakeup Frame Filter. | R/W | 0b |
| 1 | Magic Packet Enable (MPEN) When set, Magic Packet wakeup mode is enabled. | R/W | 0b |
| 0 | (LAN9500A/LAN9500Ai ONLY, Otherwise RESERVED) Broadcast Wakeup Enable (BCAST_EN) When set, remote wakeup mode is enabled and the MAC is capable of waking up from a broadcast frame. | R/W | 0b |

7.4.13 CHECKSUM OFFLOAD ENGINE CONTROL REGISTER (COE_CR)

Address: 130h Size: 32 bits

This register controls the RX and TX checksum offload engines.

| Bits | Description | Type | Default |
|-------|---|------|---------|
| 31:17 | RESERVED | RO | - |
| 16 | TX Checksum Offload Engine Enable (TX_COE_EN) TX_COE_EN may only be changed if the TX path is disabled. If it is desired to change this value during run time, it is safe to do so only after the MAC is disabled and the TLI is empty. 0 = The TXCOE is bypassed 1 = The TXCOE is enabled | R/W | 0b |
| 15:2 | RESERVED | RO | - |
| 1 | RX Checksum Offload Engine Mode (RX_COE_MODE) This register indicates whether the COE will check for VLAN tags or a SNAP header prior to beginning its checksum calculation. In its default mode, the calculation will always begin 14 bytes into the frame. RX_COE_MODE may only be changed if the RX path is disabled. If it is desired to change this value during run time, it is safe to do so only after the MAC is disabled and the TLI is empty. 0 = Begin checksum calculation after first 14 bytes of Ethernet Frame 1 = Begin checksum calculation at start of L3 packet by adjusting for VLAN tags and/or SNAP header. | R/W | 0b |
| 0 | RX Checksum Offload Engine Enable (RX_COE_EN) RX_COE_EN may only be changed if the RX path is disabled. If it is desired to change this value during run time, it is safe to do so only after the MAC is disabled and the TLI is empty. 0 = The RXCOE is bypassed 1 = The RXCOE is enabled | R/W | 0b |

LAN950x

7.5 PHY Registers

The PHY registers are not memory mapped. These registers are accessed indirectly through the MAC via the MII_ACCESS and MII_DATA registers. An index is used to access individual PHY registers. PHY Register Indexes are shown in [Table 7-6, "PHY Control and Status Register"](#) below.

Note: The NASR (**Not Affected by Software Reset**) designation is only applicable when bit 15 of the PHY Basic Control Register (Reset) is set.

TABLE 7-6: PHY CONTROL AND STATUS REGISTER

| Index (In Decimal) | Register Name |
|-----------------------|--|
| 0 | Basic Control Register |
| 1 | Basic Status Register |
| 2 | PHY Identifier 1 |
| 3 | PHY Identifier 2 |
| 4 | Auto-Negotiation Advertisement Register |
| 5 | Auto-Negotiation Link Partner Ability Register |
| 6 | Auto-Negotiation Expansion Register |
| 16 | EDPD NLP / Crossover Time Configuration Register (LAN9500A/LAN9500Ai ONLY) |
| 17 | Mode Control/Status Register |
| 18 | Special Modes |
| 27 | Control / Status Indication Register |
| 29 | Interrupt Source Register |
| 30 | Interrupt Mask Register |
| 31 | PHY Special Control/Status Register |

7.5.1 BASIC CONTROL REGISTER

Index (In Decimal): 0

Size: 16 bits

| Bits | Description | Type | Default |
|------|---|------|---------|
| 15 | PHY Soft Reset 1 = PHY software reset. Bit is self-clearing. When setting this bit do not set other bits in this register. Note: The PHY will be in the normal mode after a PHY software reset. | SC | 0b |
| 14 | Loopback 0 = normal operation 1 = loopback mode | R/W | 0b |
| 13 | Speed Select 0 = 10Mbps 1 = 100Mbps Note: Ignored if Auto Negotiation is enabled (0.12 = 1). | R/W | 1b |
| 12 | Auto-Negotiation Enable 0 = disable auto-negotiate process 1 = enable auto-negotiate process (overrides 0.13 and 0.8) | R/W | 1b |
| 11 | Power Down 0 = normal operation 1 = General power down mode Note: The Auto-Negotiation Enable must be cleared before setting the Power Down. | R/W | 0b |

8.0 OPERATIONAL CHARACTERISTICS

8.1 Absolute Maximum Ratings*

| | |
|--|--------------------------------|
| Supply Voltage (VDD33IO, VDD33A) (Note 8-1) | 0V to +3.6V |
| Positive voltage on signal pins, with respect to ground (Note 8-2) | +6V |
| Negative voltage on signal pins, with respect to ground (Note 8-3) | -0.5V |
| Positive voltage on XI, with respect to ground | +4.6V |
| Positive voltage on XO, with respect to ground | +2.5V |
| Ambient Operating Temperature in Still Air (T _A) | Note 8-4 |
| Storage Temperature | -55°C to +150°C |
| Lead Temperature Range | Refer to JEDEC Spec. J-STD-020 |
| HBM ESD Performance | Note 8-5 |
| IEC61000-4-2 Contact Discharge ESD Performance (Note 8-6) | +/-8kV |
| IEC61000-4-2 Air-Gap Discharge ESD Performance (Note 8-6) | +/-15kV |

Note 8-1 When powering this device from laboratory or system power supplies, it is important that the absolute maximum ratings not be exceeded or device failure can result. Some power supplies exhibit voltage spikes on their outputs when AC power is switched on or off. In addition, voltage transients on the AC power line may appear on the DC output. If this possibility exists, it is suggested that a clamp circuit be used.

Note 8-2 This rating does not apply to the following pins: XI, XO, EXRES, USBRBIAS.

Note 8-3 This rating does not apply to the following pins: EXRES, USBRBIAS.

Note 8-4 0°C to +70°C for commercial version, -40°C to +85°C for industrial version.

Note 8-5 +/-8kV for LAN9500/LAN9500i, +/-5kV for LAN9500A/LAN9500Ai

Note 8-6 Performed by independent 3rd party test facility.

*Stresses exceeding those listed in this section could cause permanent damage to the device. This is a stress rating only. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Functional operation of the device at any condition exceeding those indicated in Section 8.2, "Operating Conditions**", Section 8.4, "DC Specifications", or any other applicable section of this specification is not implied. Note, device signals are *NOT* 5 volt tolerant unless specified otherwise.

8.2 Operating Conditions**

| | |
|--|-----------------|
| Supply Voltage (VDD33A, VDD33BIAS, VDD33IO) | +3.3V +/- 300mV |
| Ambient Operating Temperature in Still Air (T _A) | Note 8-4 |

**Proper operation of the device is guaranteed only within the ranges specified in this section.

8.3 Power Consumption

This section details the power consumption of the device as measured during various modes of operation. Power consumption values are provided for both the device-only, and for the device plus Ethernet components. Power dissipation is determined by temperature, supply voltage, and external source/sink requirements.

Note: All current consumption and power dissipation values were measured at VDD33IO and VDD33A equal to 3.3V.

LAN950x

8.3.1 SUSPEND0

TABLE 8-1: POWER CONSUMPTION/DISSIPATION - SUSPEND0 (LAN9500/LAN9500I)

| Parameter | MIN | Typical | MAX | Unit |
|--|-----|---------|-----|------|
| Supply current (VDD33IO, VDD33A) (Device Only) | | 78 | | mA |
| Power Dissipation (Device Only) | | 257 | | mW |
| Power Dissipation (Device and Ethernet components) | | 395 | | mW |

TABLE 8-2: POWER CONSUMPTION/DISSIPATION - SUSPEND0 (LAN9500A/LAN9500AI)

| Parameter | MIN | Typical | MAX | Unit |
|--|-----|---------|-----|------|
| Supply current (VDD33IO, VDD33A) (Device Only) | | 46 | | mA |
| Power Dissipation (Device Only) | | 152 | | mW |
| Power Dissipation (Device and Ethernet components) | | 291 | | mW |

8.3.2 SUSPEND1

TABLE 8-3: POWER CONSUMPTION/DISSIPATION - SUSPEND1 (LAN9500/LAN9500I)

| Parameter | MIN | Typical | MAX | Unit |
|--|-----|---------|-----|------|
| Supply current (VDD33IO, VDD33A) (Device Only) | | 20 | | mA |
| Power Dissipation (Device Only) | | 66 | | mW |
| Power Dissipation (Device and Ethernet components) | | 66 | | mW |

TABLE 8-4: POWER CONSUMPTION/DISSIPATION - SUSPEND1 (LAN9500A/LAN9500AI)

| Parameter | MIN | Typical | MAX | Unit |
|--|-----|---------|-----|------|
| Supply current (VDD33IO, VDD33A) (Device Only) | | 7.0 | | mA |
| Power Dissipation (Device Only) | | 23.5 | | mW |
| Power Dissipation (Device and Ethernet components) | | 27.5 | | mW |

8.3.3 SUSPEND2

TABLE 8-5: POWER CONSUMPTION/DISSIPATION - SUSPEND2 (LAN9500/LAN9500I)

| Parameter | MIN | Typical | MAX | Unit |
|--|-----|---------|-----|------|
| Supply current (VDD33IO, VDD33A) (Device Only) | | 0.624 | | mA |
| Power Dissipation (Device Only) | | 2.1 | | mW |
| Power Dissipation (Device and Ethernet components) | | 2.1 | | mW |

TABLE 8-6: POWER CONSUMPTION/DISSIPATION - SUSPEND2 (LAN9500A/LAN9500AI)

| Parameter | MIN | Typical | MAX | Unit |
|--|-----|---------|-----|------|
| Supply current (VDD33IO, VDD33A) (Device Only) | | 1.6 | | mA |
| Power Dissipation (Device Only) | | 5.3 | | mW |
| Power Dissipation (Device and Ethernet components) | | 5.3 | | mW |

Note: SUSPEND2 power consumption/dissipation values were measured in bus-powered mode.

8.3.4 SUSPEND3

Note: SUSPEND3 not supported by LAN9500/LAN9500i.

TABLE 8-7: POWER CONSUMPTION/DISSIPATION - SUSPEND3 (LAN9500A/LAN9500AI)

| Parameter | MIN | Typical | MAX | Unit |
|--|-----|---------|-----|------|
| Supply current (VDD33IO, VDD33A) (Device Only) | | 24.5 | | mA |
| Power Dissipation (Device Only) | | 81.2 | | mW |
| Power Dissipation (Device and Ethernet components) | | 85.1 | | mW |

8.3.5 OPERATIONAL

TABLE 8-8: OPERATIONAL POWER CONSUMPTION/DISSIPATION (LAN9500/LAN9500I)

| Parameter | MIN | Typical | MAX | Unit |
|--|-----|---------|-----|------|
| 100BASE-TX Full Duplex (USB High-Speed) | | | | |
| Supply current (VDD33IO, VDD33A) (Device Only) | | 143 | | mA |
| Power Dissipation (Device Only) | | 474 | | mW |

Note 8-13 Min/max voltages guaranteed as measured with 100Ω resistive load.

8.5 AC Specifications

This section details the various AC timing specifications of the device.

- Note 1:** The MII timing adheres to the IEEE 802.3 specification. Refer to the IEEE 802.3 specification for additional MII timing information.
- 2:** The USBDP and USBDM pin timing adheres to the USB 2.0 specification. Refer to the Universal Serial Bus Revision 2.0 specification for detailed USB timing information.

8.5.1 EQUIVALENT TEST LOAD

Output timing specifications assume the 25pF equivalent test load illustrated in [Figure 8-1](#) below, unless otherwise specified.

FIGURE 8-1: OUTPUT EQUIVALENT TEST LOAD

LAN950x

8.5.2 POWER-ON CONFIGURATION STRAP VALID TIMING

Figure 8-2 illustrates the configuration strap valid timing requirement in relation to power-on. In order for valid configuration strap values to be read at power-on, the following timing requirements must be met.

FIGURE 8-2: POWER-ON CONFIGURATION STRAP VALID TIMING

TABLE 8-15: POWER-ON CONFIGURATION STRAP VALID TIMING

| Symbol | Description | MIN | TYP | MAX | Units |
|-----------|--------------------------------|-----|-----|-----|-------|
| t_{cfg} | Configuration strap valid time | | | 15 | mS |

8.5.3 RESET AND CONFIGURATION STRAP TIMING

Figure 8-3 illustrates the nRESET pin timing requirements and its relation to the configuration strap pins and output drive. Assertion of nRESET is not a requirement. However, if used, it must be asserted for the minimum period specified.

FIGURE 8-3: NRESET RESET PIN TIMING

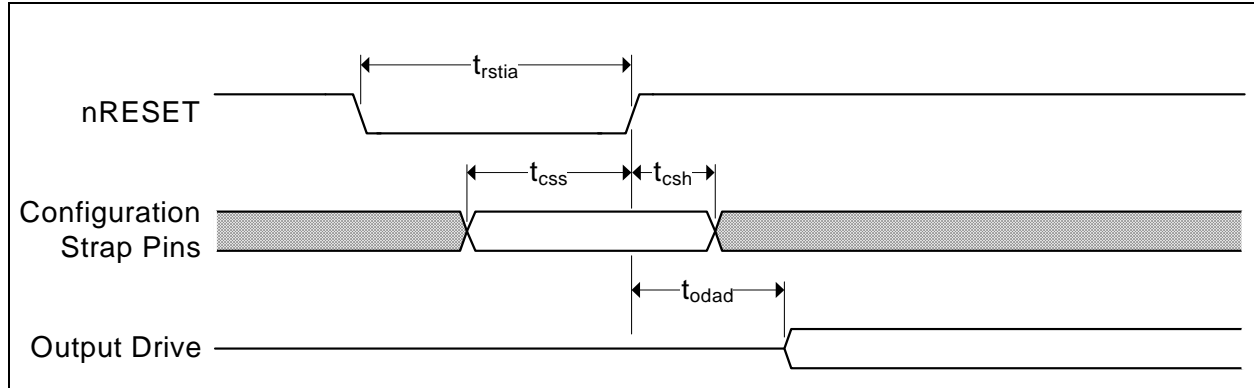

TABLE 8-16: NRESET RESET PIN TIMING VALUES

| Symbol | Description | MIN | TYP | MAX | Units |
|-------------|--|-----|-----|-----|---------|
| t_{rstia} | nRESET input assertion time | 1 | | | μ S |
| t_{css} | Configuration strap pins setup to nRESET deassertion | 200 | | | nS |
| t_{csh} | Configuration strap pins hold after nRESET deassertion | 10 | | | nS |
| t_{odad} | Output drive after deassertion | 30 | | | nS |

LAN950x

8.5.4 EEPROM TIMING

The following specifies the EEPROM timing requirements for the device:

FIGURE 8-4: EEPROM TIMING

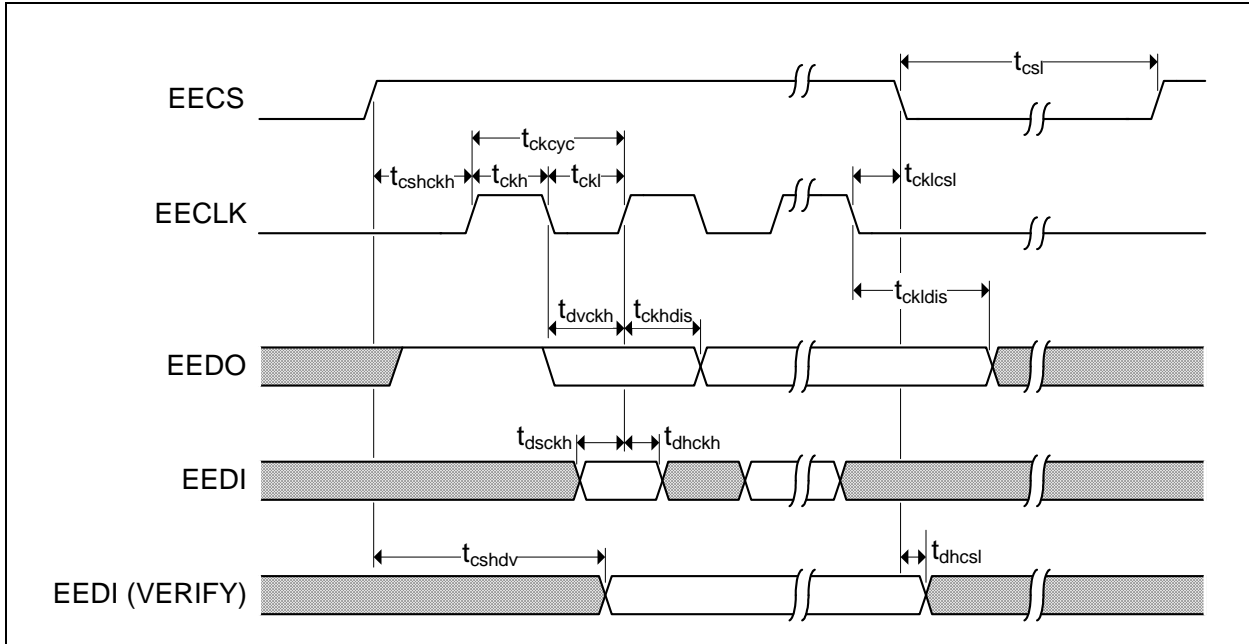

TABLE 8-17: EEPROM TIMING VALUES

| Symbol | Description | MIN | TYP | MAX | Units |
|--------------|--|------|-----|------|-------|
| t_{ckcyc} | EECLK Cycle time | 1110 | | 1130 | ns |
| t_{ckh} | EECLK High time | 550 | | 570 | ns |
| t_{ckl} | EECLK Low time | 550 | | 570 | ns |
| t_{cshckh} | EECS high before rising edge of EECLK | 1070 | | | ns |
| t_{cklcs1} | EECLK falling edge to EECS low | 30 | | | ns |
| t_{dvckh} | EEDO valid before rising edge of EECLK | 550 | | | ns |
| t_{ckhdis} | EEDO disable after rising edge EECLK | 550 | | | ns |
| t_{dsckh} | EEDI setup to rising edge of EECLK | 90 | | | ns |
| t_{dhckh} | EEDI hold after rising edge of EECLK | 0 | | | ns |
| t_{ckldis} | EECLK low to data disable (OUTPUT) | 580 | | | ns |
| t_{cshdv} | EEDIO valid after EECS high (VERIFY) | | | 600 | ns |
| t_{dhcsl} | EEDIO hold after EECS low (VERIFY) | 0 | | | ns |
| t_{csl} | EECS low | 1070 | | | ns |

8.5.5 MII INTERFACE TIMING

This section specifies the MII interface transmit and receive timing.

FIGURE 8-5: MII TRANSMIT TIMING

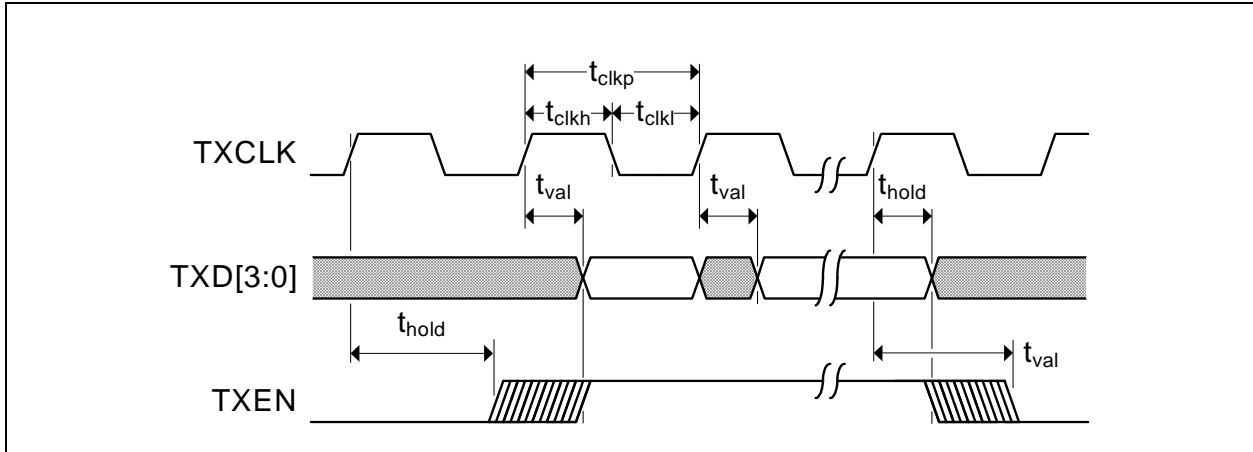

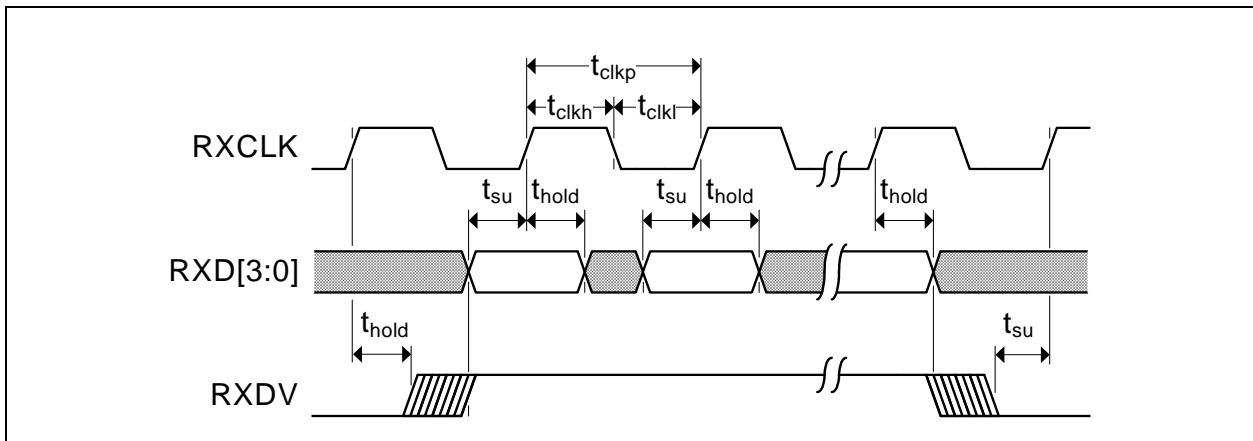

TABLE 8-18: MII TRANSMIT TIMING VALUES

| Symbol | Description | MIN | TYP | MAX | Notes |
|------------|---|------------------|------------------|-----|-----------|
| t_{clkp} | TXCLK period | 40 | | ns | |
| t_{clkh} | TXCLK high time | $t_{clkp} * 0.4$ | $t_{clkp} * 0.6$ | ns | |
| t_{clkl} | TXCLK low time | $t_{clkp} * 0.4$ | $t_{clkp} * 0.6$ | ns | |
| t_{val} | TXD[3:0], TXEN output valid from rising edge of TXCLK | | 22.0 | ns | Note 8-14 |
| t_{hold} | TXD[3:0], TXEN output hold from rising edge of TXCLK | 0 | | ns | Note 8-14 |

Note 8-14 Timing was designed for system load between 10 pf and 25 pf.

FIGURE 8-6: MII RECEIVE TIMING

LAN950x

TABLE 8-19: MII RECEIVE TIMING VALUES

| Symbol | Description | MIN | TYP | MAX | Notes |
|------------|---|------------------|------------------|-----|---------------------------|

Note 8-15 Timing was designed for system load between 10 pf and 25 pf.

8.5.6 TURBO MII INTERFACE TIMING

This section specifies the Turbo MII interface transmit and receive timing.

FIGURE 8-7: TURBO MII TRANSMIT TIMING

TABLE 8-20: TURBO MII TRANSMIT TIMING VALUES

| Symbol | Description | MIN | TYP | MAX | Notes |
|------------|---|------------------|------------------|-----|-----------|
| t_{clkp} | TXCLK period | 20 | | ns | |
| t_{clkh} | TXCLK high time | $t_{clkp} * 0.4$ | $t_{clkp} * 0.6$ | ns | |
| t_{clkl} | TXCLK low time | $t_{clkp} * 0.4$ | $t_{clkp} * 0.6$ | ns | |
| t_{val} | TXD[3:0], TXEN output valid from rising edge of TXCLK | | 12.5 | ns | Note 8-16 |
| t_{hold} | TXD[3:0], TXEN output hold from rising edge of TXCLK | 1.5 | | ns | Note 8-16 |

Note 8-16 Timing was designed for system load between 10 pf and 15 pf.

FIGURE 8-8: TURBO MII RECEIVE TIMING

LAN950x

TABLE 8-21: TURBO MII RECEIVE TIMING VALUES

| Symbol | Description | MIN | TYP | MAX | Notes |
|------------|---|------------------|------------------|-----|---------------------------|
| t_{clkp} | RXCLK period | 20 | | ns | |
| t_{clkh} | RXCLK high time | $t_{clkp} * 0.4$ | $t_{clkp} * 0.6$ | ns | |
| t_{clkl} | RXCLK low time | $t_{clkp} * 0.4$ | $t_{clkp} * 0.6$ | ns | |
| t_{su} | RXD[3:0], RXDV setup time to rising edge of RXCLK | 5.5 | | ns | Note 8-17 |
| t_{hold} | RXD[3:0], RXDV hold time after rising edge of RXCLK | 0 | | ns | Note 8-17 |

Note 8-17 Timing was designed for system load between 10 pf and 15 pf.

8.5.7 JTAG TIMING

This section specifies the JTAG timing of the device.

FIGURE 8-9: JTAG TIMING

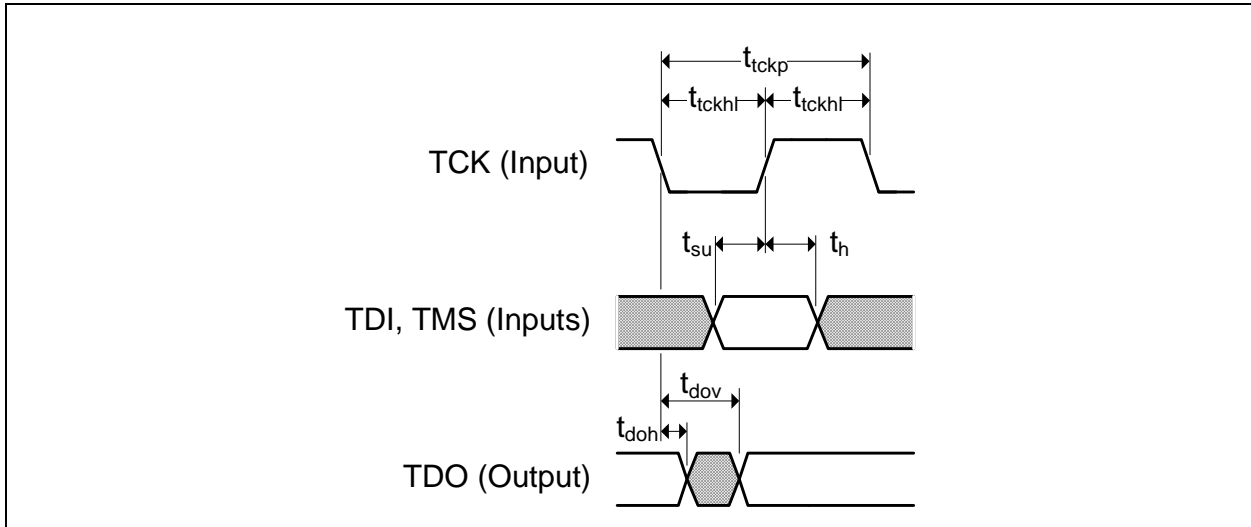

TABLE 8-22: JTAG TIMING VALUES

| Symbol | Description | MIN | TYP | MAX | Notes |
|---------------|--|------------------|------------------|-----|-------|
| t_{tckp} | TCK clock period | 66.67 | | ns | |
| t_{tckhl} | TCK clock high/low time | $t_{tckp} * 0.4$ | $t_{tckp} * 0.6$ | ns | |
| t_{su} | TDI, TMS setup to TCK rising edge | 10 | | ns | |
| t_h | TDI, TMS hold from TCK rising edge | 10 | | ns | |
| t_{dov} | TDO output valid from TCK falling edge | | 16 | ns | |
| $t_{doinvld}$ | TDO output invalid from TCK falling edge | 0 | | ns | |

LAN950x

8.6 Clock Circuit

The device can accept either a 25MHz crystal (preferred) or a 25MHz single-ended clock oscillator (+/- 50ppm) input. If the single-ended clock oscillator method is implemented, XO should be left unconnected and XI should be driven with a nominal 0-3.3V clock signal. The input clock duty cycle is 40% minimum, 50% typical and 60% maximum.

It is recommended that a crystal utilizing matching parallel load capacitors be used for the crystal input/output signals (XI/XO). For the LAN9500A/LAN9500Ai, either a 300uW or 100uW 25MHz crystal may be utilized. For the LAN9500/LAN9500i, only a 300uW 25MHz crystal may be utilized. The 300uW 25MHz crystal specifications are detailed in [Section 8.6.1, "300uW 25MHz Crystal Specifications," on page 204](#). The 100uW 25MHz crystal specifications are detailed in [Section 8.6.2, "100uW 25MHz Crystal Specifications \(LAN9500A/LAN9500Ai Only\)," on page 205](#).

8.6.1 300uW 25MHz CRYSTAL SPECIFICATIONS

When utilizing a 300uW 25MHz crystal, the following circuit design ([Figure 8-10](#)) and specifications ([Table 8-23](#)) are required to ensure proper operation.

FIGURE 8-10: 300uW 25MHz CRYSTAL CIRCUIT

TABLE 8-23: 300uW CRYSTAL SPECIFICATIONS

| Parameter | Symbol | MIN | NOM | MAX | Units | Notes |
|-------------------------------|------------|---------------------------|-----------|---------------------------|-------|---------------------------|
| Crystal Cut | | AT, typ | | | | |
| Crystal Oscillation Mode | | Fundamental Mode | | | | |
| Crystal Calibration Mode | | Parallel Resonant Mode | | | | |
| Frequency | F_{fund} | - | 25.000 | - | MHz | |
| Frequency Tolerance @ 25°C | F_{tol} | - | - | +/-50 | PPM | Note 8-18 |
| Frequency Stability Over Temp | F_{temp} | - | - | +/-50 | PPM | Note 8-18 |
| Frequency Deviation Over Time | F_{age} | - | +/-3 to 5 | - | PPM | Note 8-19 |
| Total Allowable PPM Budget | | - | - | +/-50 | PPM | Note 8-20 |
| Shunt Capacitance | C_O | - | 7 typ | - | pF | |
| Load Capacitance | C_L | - | 20 typ | - | pF | |
| Drive Level | P_W | 300 | - | - | uW | |
| Equivalent Series Resistance | R_1 | - | - | 50 | Ohm | |
| Operating Temperature Range | | Note 8-21 | - | Note 8-22 | °C | |
| XI Pin Capacitance | | - | 3 typ | - | pF | Note 8-23 |
| XO Pin Capacitance | | - | 3 typ | - | pF | Note 8-23 |

Note 8-18 The maximum allowable values for Frequency Tolerance and Frequency Stability are application dependent. Since any particular application must meet the IEEE +/-50 PPM Total PPM Budget, the combination of these two values must be approximately +/-45 PPM (allowing for aging).

- Note 8-19** Frequency Deviation Over Time is also referred to as Aging.
- Note 8-20** The total deviation for the Transmitter Clock Frequency is specified by IEEE 802.3u as +/- 50 PPM.
- Note 8-21** 0°C for commercial version, -40°C for industrial version.
- Note 8-22** +70°C for commercial version, +85°C for industrial version.
- Note 8-23** This number includes the pad, the bond wire and the lead frame. PCB capacitance is not included in this value. The XO/XI pin and PCB capacitance values are required to accurately calculate the value of the two external load capacitors. These two external load capacitors determine the accuracy of the 25.000 MHz frequency.

8.6.2 100UW 25MHZ CRYSTAL SPECIFICATIONS (LAN9500A/LAN9500AI ONLY)

When utilizing a 100uW 25MHz crystal (LAN9500A/LAN9500Ai only), the following circuit design (Figure 8-11) and specifications (Table 8-24) are required to ensure proper operation.

FIGURE 8-11: 100UW 25MHZ CRYSTAL CIRCUIT

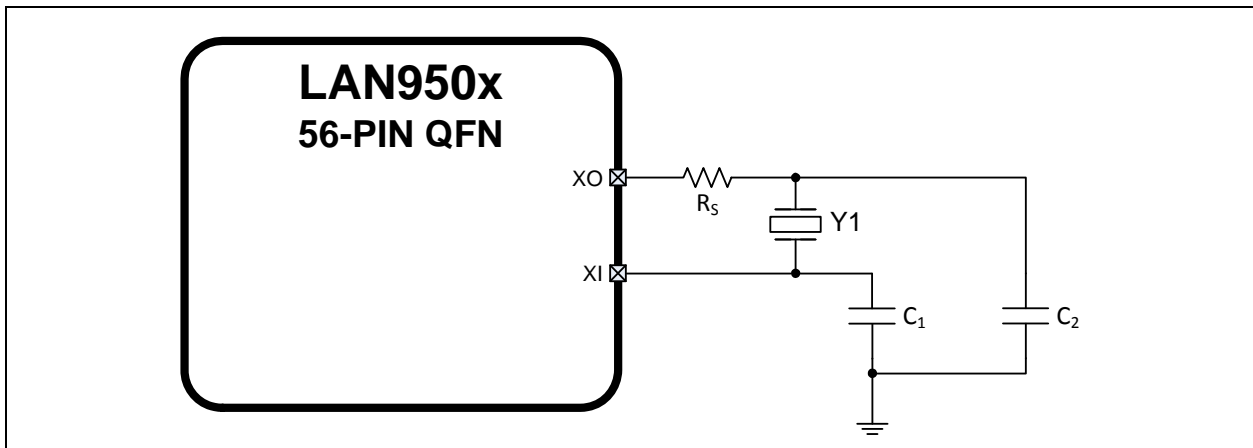

TABLE 8-24: 100UW CRYSTAL SPECIFICATIONS

| Parameter | Symbol | MIN | NOM | MAX | Units | Notes |
|-------------------------------|------------|------------------------|-----------|-----------|-------|-----------|
| Crystal Cut | | AT, typ | | | | |
| Crystal Oscillation Mode | | Fundamental Mode | | | | |
| Crystal Calibration Mode | | Parallel Resonant Mode | | | | |
| Frequency | F_{fund} | - | 25.000 | - | MHz | |
| Frequency Tolerance @ 25°C | F_{tol} | - | - | +/-50 | PPM | Note 8-24 |
| Frequency Stability Over Temp | F_{temp} | - | - | +/-50 | PPM | Note 8-24 |
| Frequency Deviation Over Time | F_{age} | - | +/-3 to 5 | - | PPM | Note 8-25 |
| Total Allowable PPM Budget | | - | - | +/-50 | PPM | Note 8-26 |
| Shunt Capacitance | C_O | - | - | 5 | pF | |
| Load Capacitance | C_L | 8 | - | 12 | pF | |
| Drive Level | P_W | - | 100 | - | uW | Note 8-27 |
| Equivalent Series Resistance | R_1 | - | - | 80 | Ohm | |
| XO Series Resistor | R_s | 495 | 500 | 505 | Ohm | |
| Operating Temperature Range | | Note 8-28 | - | Note 8-29 | °C | |

LAN950x

TABLE 8-24: 100UW CRYSTAL SPECIFICATIONS (CONTINUED)

| Parameter | Symbol | MIN | NOM | MAX | Units | Notes |
|--------------------|--------|-----|-------|-----|-------|---------------------------|
| XI Pin Capacitance | | - | 3 typ | - | pF | Note 8-30 |
| XO Pin Capacitance | | - | 3 typ | - | pF | Note 8-30 |

Note 8-24 The maximum allowable values for Frequency Tolerance and Frequency Stability are application dependent. Since any particular application must meet the IEEE +/-50 PPM Total PPM Budget, the combination of these two values must be approximately +/-45 PPM (allowing for aging).

Note 8-25 Frequency Deviation Over Time is also referred to as Aging.

Note 8-26 The total deviation for the Transmitter Clock Frequency is specified by IEEE 802.3u as +/- 50 PPM.

Note 8-27 The crystal must support 100uW operation to utilize this circuit.

Note 8-28 0°C for commercial version, -40°C for industrial version.

Note 8-29 +70°C for commercial version, +85°C for industrial version.

Note 8-30 This number includes the pad, the bond wire and the lead frame. PCB capacitance is not included in this value. The XO/XI pin and PCB capacitance values are required to accurately calculate the value of the two external load capacitors (C_1 and C_2 in [Figure 8-11](#)). The external load capacitors, C_1 and C_2 , determine the accuracy of the 25.000 MHz frequency.

9.0 PACKAGE OUTLINE

FIGURE 9-1: LAN950X 56-QFN PACKAGE DEFINITION (1 OF 2)

FIGURE 9-2: LAN950X 56-QFN PACKAGE DEFINITION (2 OF 2)

APPENDIX A: DATA SHEET REVISION HISTORY

TABLE A-1: REVISION HISTORY

| Revision Level and Date | Section/Figure/Entry | Correction |
|---------------------------|--|---|
| DS00001875A (01-07-15) | Replaces previous SMSC version Rev. 1.2 (07-15-11); package outlines replaced, Product Information System page replaces "ordering information", reel size changed from 4,000 to 3,000. | |
| | Table 1-1, "LAN950x Family Differences," on page 4 | Added LAN9500A/LAN9500Ai low power 100uW crystal support as differentiating factor. |
| | Section 8.6, "Clock Circuit," on page 204 | Added new 100uW crystal specifications and circuit diagram (LAN9500A/LAN9500Ai only). The section is now split into two subsections, one for 300uW crystals and the other for 100uW crystals. |
| Rev. 1.2 (07-15-11) | Ordering Information | Added tape and reel options. |
| Rev 1.2 (07-13-11) | FIGURE 4-1: Power Connections on page 24 | Substituted "u" and "ohm" for Greek symbols mu and omega that were not properly displayed because of font issues. |
| | Section 8.5.7, "JTAG Timing," on page 203 | Added section. |
| | Section 5.5.8.1, "TX Checksum Calculation," on page 69 | Added note stating TX Checksum calculation should not be used for UDP packets under IPv6. |
| Rev. 1.1 (11-05-10) | Section 7.5.8, "EDPD NLP / Crossover Time Configuration Register," on page 182 | Added new register with EDPD NLP and crossover time configuration bits. |
| | Table 7-6, "PHY Control and Status Register," on page 174 | Added register 16 to the register map |
| | Section 5.6.7, "HP Auto-MDIX," on page 76 | Added note related to auto-MDIX crossover time extension bit of the EDPD NLP / Crossover Time Configuration Register . |
| | Section 5.6.8.2, "Energy Detect Power-Down (EDPD)," on page 78 | Added extra paragraph describing the NLP configuration bits of the EDPD NLP / Crossover Time Configuration Register . |
| | Section 7.5.9, "Mode Control/Status Register," on page 183 | Added note to EDPWRDOWN bit regarding NLP configuration bits. |
| Rev. 1.0 (05-17-10) | Initial Release. | |

LAN950x

THE MICROCHIP WEB SITE

Microchip provides online support via our WWW site at www.microchip.com. This web site is used as a means to make files and information easily available to customers. Accessible by using your favorite Internet browser, the web site contains the following information:

- **Product Support** – Data sheets and errata, application notes and sample programs, design resources, user's guides and hardware support documents, latest software releases and archived software
- **General Technical Support** – Frequently Asked Questions (FAQ), technical support requests, online discussion groups, Microchip consultant program member listing
- **Business of Microchip** – Product selector and ordering guides, latest Microchip press releases, listing of seminars and events, listings of Microchip sales offices, distributors and factory representatives

CUSTOMER CHANGE NOTIFICATION SERVICE

Microchip's customer notification service helps keep customers current on Microchip products. Subscribers will receive e-mail notification whenever there are changes, updates, revisions or errata related to a specified product family or development tool of interest.

To register, access the Microchip web site at www.microchip.com. Under "Support", click on "Customer Change Notification" and follow the registration instructions.

CUSTOMER SUPPORT

Users of Microchip products can receive assistance through several channels:

- Distributor or Representative
- Local Sales Office
- Field Application Engineer (FAE)
- Technical Support

Customers should contact their distributor, representative or field application engineer (FAE) for support. Local sales offices are also available to help customers. A listing of sales offices and locations is included in the back of this document.

Technical support is available through the web site at: <http://www.microchip.com/support>

PRODUCT IDENTIFICATION SYSTEM

To order or obtain information, e.g., on pricing or delivery, refer to the factory or the listed sales office.

| <u>PART NO.</u> | <u>[X]</u> | - | <u>XXX</u> | - | <u>[X]⁽¹⁾</u> |
|---|---|---|------------|---|--------------------------|
| Device | Temperature Range | | Package | | Tape and Reel Option |
| Device: | LAN9500, LAN9500i, LAN9500A, LAN9500Ai | | | | |
| Temperature Range: | Blank = 0°C to +70°C (Extended Commercial) i = -40°C to +85°C (Industrial) | | | | |
| Package: | ABZJ = 56-pin QFN (Tray) ABZJ-TR = 56-pin QFN (Tape & Reel) | | | | |
| Tape and Reel Option: | Blank = Standard packaging (tray) TR = Tape and Reel ⁽¹⁾ | | | | |
| <p>Examples:</p> <ul style="list-style-type: none"> a) LAN9500-ABZJ 56-pin RoHS compliant package Extended commercial temperature b) LAN9500-ABZJ-TR 56-pin RoHS compliant package Extended commercial temperature c) LAN9500i-ABZJ 56-pin RoHS compliant package Industrial temperature d) LAN9500i-ABZJ-TR 56-pin RoHS compliant package Industrial temperature e) LAN9500A-ABZJ 56-pin RoHS compliant package Extended commercial temperature f) LAN9500A-ABZJ-TR 56-pin RoHS compliant package Extended commercial temperature g) LAN9500Ai-ABZJ 56-pin RoHS compliant package Industrial temperature h) LAN9500Ai-ABZJ-TR 56-pin RoHS compliant package Industrial temperature <p>Note 1: Tape and Reel identifier only appears in the catalog part number description. This identifier is used for ordering purposes and is not printed on the device package. Check with your Microchip Sales Office for package availability with the Tape and Reel option. Reel size is 3,000.</p> | | | | | |

Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.

Trademarks

The Microchip name and logo, the Microchip logo, dsPIC, FlashFlex, flexPWR, JukeBlox, KEELOQ, KEELOQ logo, Kleer, LANCheck, MediaLB, MOST, MOST logo, MPLAB, OptoLyzer, PIC, PICSTART, PIC³² logo, RightTouch, SpyNIC, SST, SST Logo, SuperFlash and UNI/O are registered trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

The Embedded Control Solutions Company and mTouch are registered trademarks of Microchip Technology Incorporated in the U.S.A.

Analog-for-the-Digital Age, BodyCom, chipKIT, chipKIT logo, CodeGuard, dsPICDEM, dsPICDEM.net, ECAN, In-Circuit Serial Programming, ICSP, Inter-Chip Connectivity, KleerNet, KleerNet logo, MiWi, MPASM, MPF, MPLAB Certified logo, MPLIB, MPLINK, MultiTRAK, NetDetach, Omniscient Code Generation, PICDEM, PICDEM.net, PICKit, PICTail, RightTouch logo, REAL ICE, SQI, Serial Quad I/O, Total Endurance, TSHARC, USBCheck, VariSense, ViewSpan, WiperLock, Wireless DNA, and ZENA are trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

SQTP is a service mark of Microchip Technology Incorporated in the U.S.A.

Silicon Storage Technology is a registered trademark of Microchip Technology Inc. in other countries.

GestIC is a registered trademarks of Microchip Technology Germany II GmbH & Co. KG, a subsidiary of Microchip Technology Inc., in other countries.

All other trademarks mentioned herein are property of their respective companies.

QUALITY MANAGEMENT SYSTEM
CERTIFIED BY DNV
== ISO/TS 16949 ==

Microchip received ISO/TS-16949:2009 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company's quality system processes and procedures are for its PIC[®] MCUs and dsPIC[®] DSCs, KEELOQ[®] code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001:2000 certified.
